Run-Time protection/enforcement

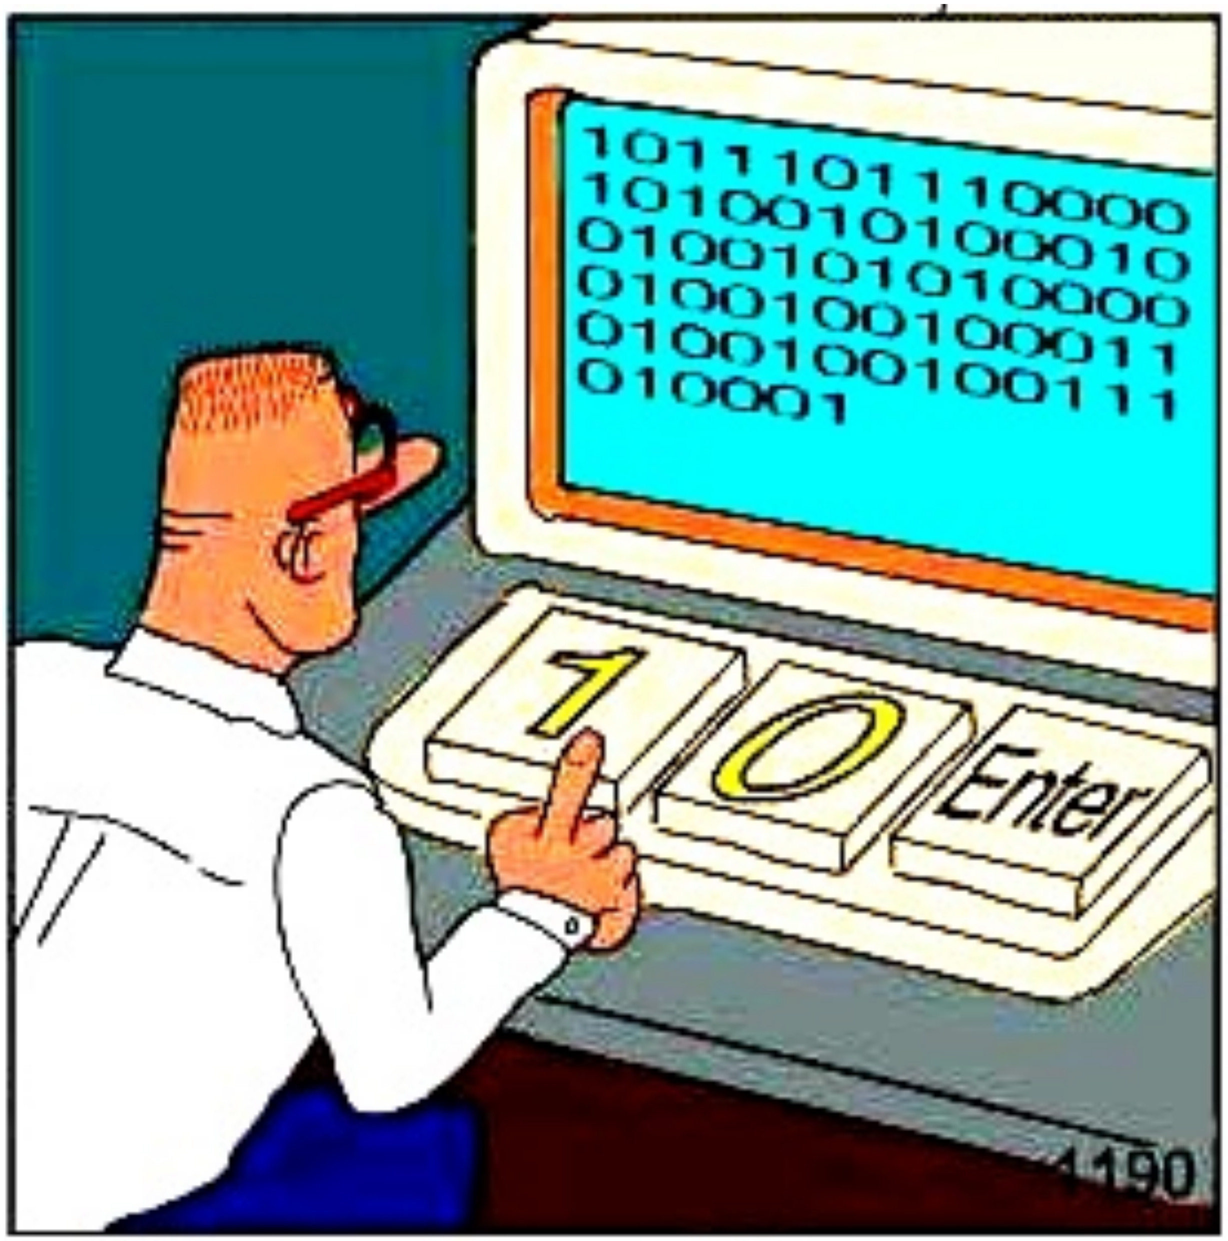
- In many instances we only have access to the binary
- How do we analyze the binary for vulnerabilities?
- How do we protect the binary from exploitation?
- This would be our topic for this lectures



REAL Programmers code in BINARY.

Why Binary Code?

- Access to the source code often is not possible:
  - Proprietary software packages
  - Stripped executables
  - Proprietary libraries: communication (MPI, PVM), linear algebra (NGA), database query (SQL libraries)
- Binary code is the only authoritative version of the program
  - Changes occurring in the compile, optimize and link steps can create non-trivial semantic differences from the source and binary
- Worms and viruses are rarely provided with source code

[B. P. Miller'06]

Binary Analysis and Editing

- **Analysis**: processing of the binary code to extract syntactic and symbolic information
  - Symbol tables (if present)
  - Decode (disassemble) instructions
  - Control-flow information: basic blocks, loops, functions
  - Data-flow information: from basic register information to highly sophisticated (and expensive) analysis

[B. P. Miller'06]

Binary Analysis and Editing

- **Binary rewriting**: static (before execution) modification of a binary program
  - Analyze the program and then insert, remove, or change the binary code, producing a new binary

- **Dynamic instrumentation**: dynamic (during execution) modification of a binary program
  - Analyze the code of the running program and then insert, remove, or change the binary code, changing the execution of the program
  - Can operate on running programs and servers

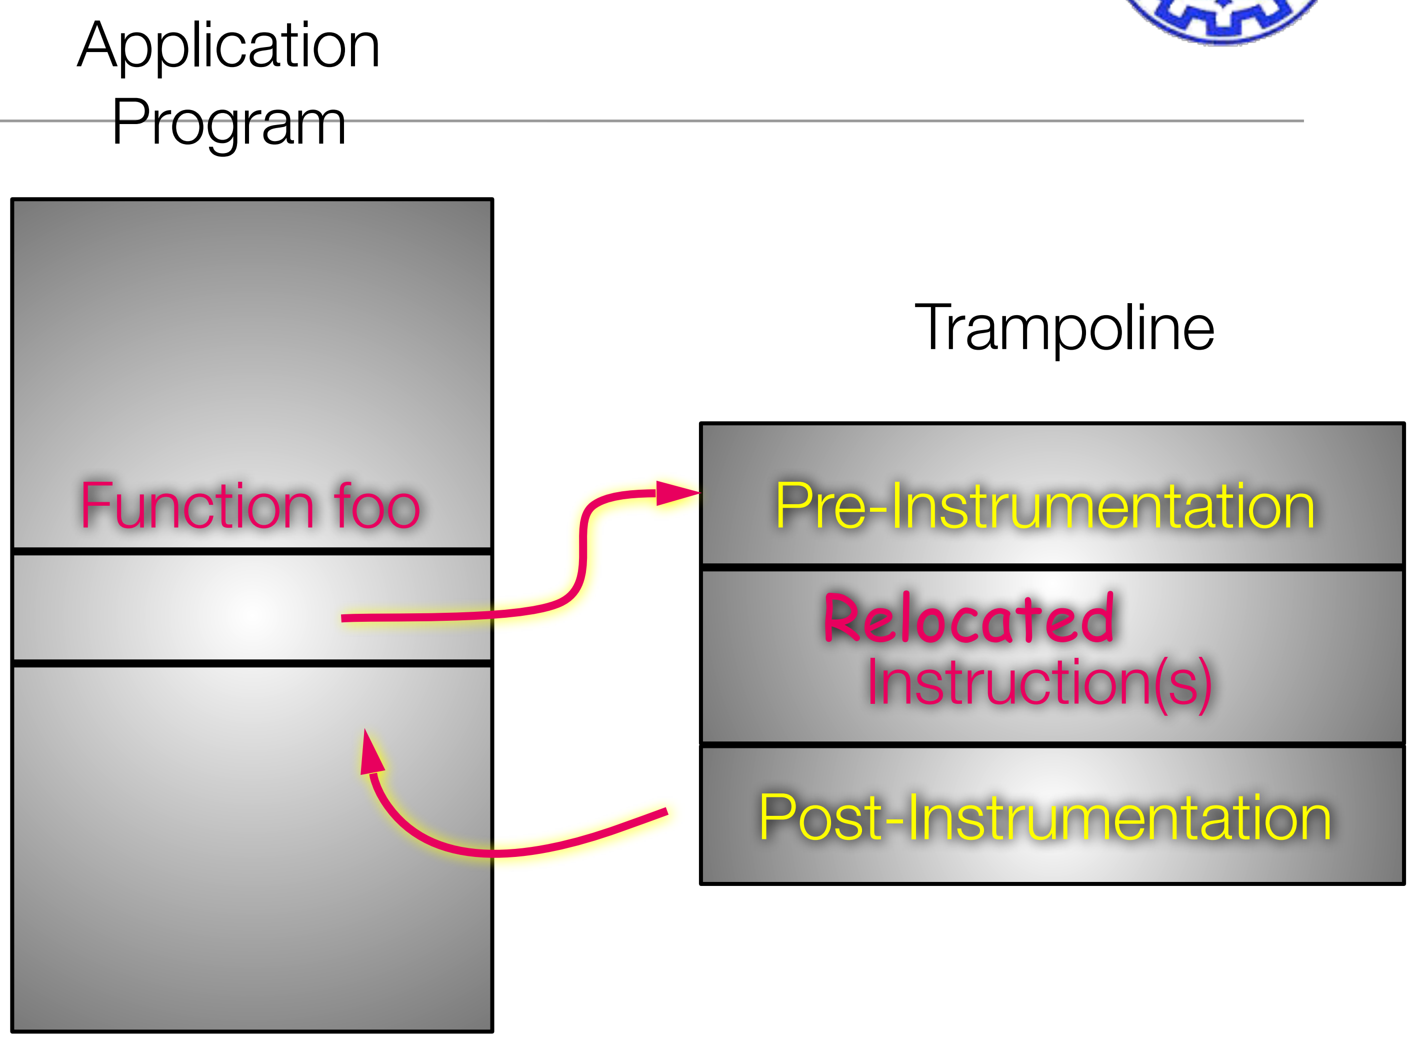
[B. P. Miller'06]

Uses of Binary Analysis and Editing

- Cyber-forensics
  - Analysis: understand the nature of malicious code
  - Binary-rewriting: produce a new version of the code that might be instrumented, sandboxed, or modified for study
  - Dynamic instrumentation: same features, but can do it interactively on an executing program
  - Hybrid static/dynamic: control execution and produce intermediate versions of the binary that can be re-executed (and further instrumented)
- Program tracing: instructions, memory accesses, function calls, system calls, . . .
- Debugging
- Testing, Performance profiling Performance modeling
- Reverse engineering

[B. P. Miller’06]

Binary patch



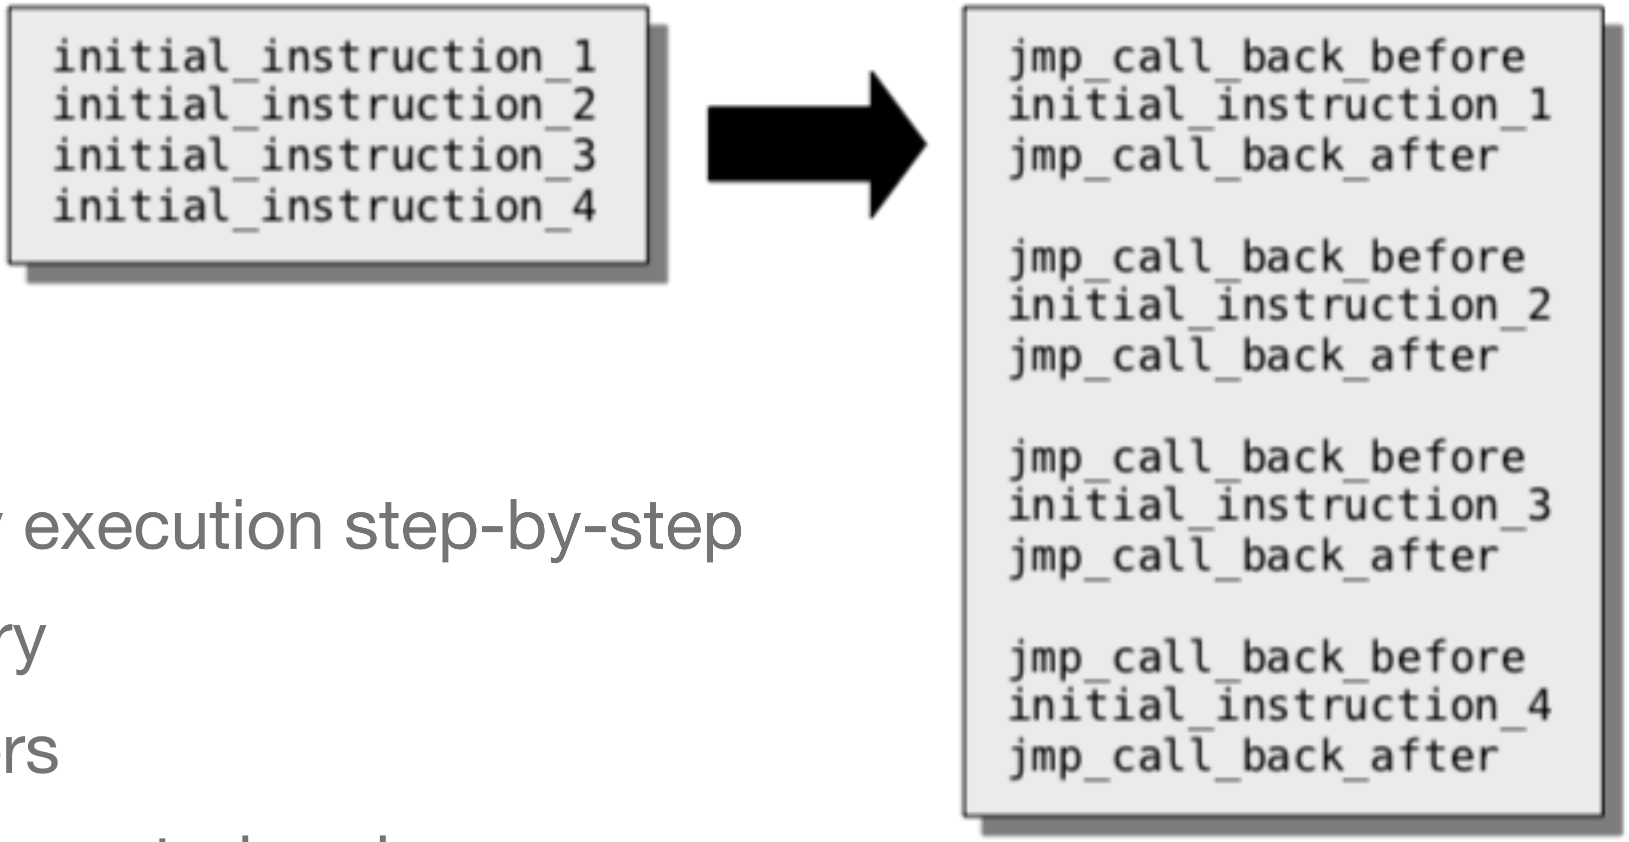
pop ecx; puts the return address to ecx
jmp ecx; jumps to the return address

After Patch:

pop ecx; puts the return address to ecx
cmp ecx , 0x08048456 ; check that we return to the right place
jne 0x41414141 ; crash
jmp ecx; effectively return

Dynamic Binary Instrumentation

- A DBI is a way to execute an external code before or/and after each instruction/routine



```
initial_instruction_1
initial_instruction_2
initial_instruction_3
initial_instruction_4
```

```
jmp_call_back_before
initial_instruction_1
jmp_call_back_after

jmp_call_back_before
initial_instruction_2
jmp_call_back_after

jmp_call_back_before
initial_instruction_3
jmp_call_back_after

jmp_call_back_before
initial_instruction_4
jmp_call_back_after
```

- With a DBI you can:
  - Analyze the binary execution step-by-step
    - Context memory
    - Context registers
  - Only analyze the executed code

[Salwan'15]

Available Tools

- Binary re-writing:
    - e.g.: Alto, Vulcan, Diablo, etc.
- Binary Instrumnetation:
    - e.g. PIN, Valgrind, DynInst, etc

Dynamic Taint Analysis for Automatic Detection, Analysis, and Signature Generation of Exploits on Commodity Software, J. Newsome and D. Song, NDSS 2005.

Motivation

- Worms exploit several software vulnerabilities
  - buffer overflow
  - “format string” vulnerability
- Attack detectors ideally should:
  - Detect new attacks and detect them early
  - Be easy to deploy
  - Few false positives and false negatives
  - Be able to automatically generate filters and sharable fingerprints

[Papadopoulos’11]

Motivation (contd.)

- Attack detectors are:
  - Coarse grained detectors
    - Detect anomalous behavior but do not provide detailed information about the vulnerability
    - Scan detectors, anomaly detectors
  - Fine grained detectors are highly desirable
    - Detect attacks on programs vulnerabilities and hence provide detailed information about the attack
    - But some require source code (typically not available for commercial software), recompilation, bounds checking, library recompilation, source code modification, etc.
  - Other options: content-based filtering (e.g., IDS' such as snort and Bro), but automatic signature generation is hard

[Papadopoulos'11]

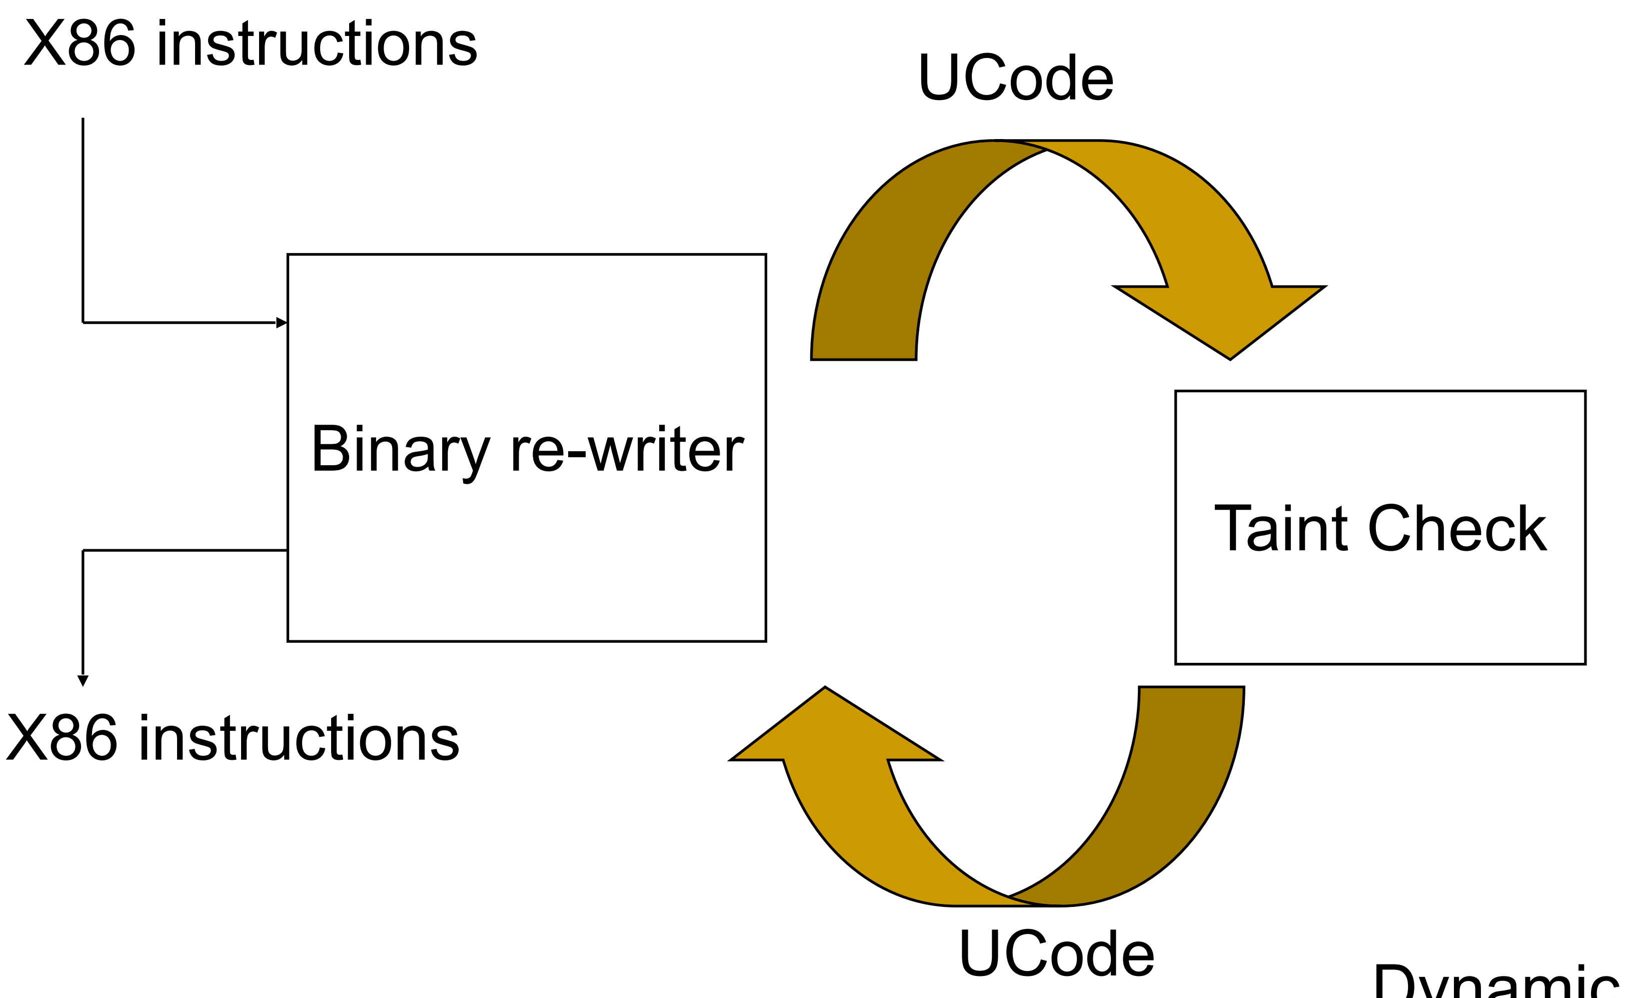
TaintCheck: Basic Ideas

- Program execution normally derived from trusted sources, not attacker input
- Mark all input data to the computer as “tainted” (e.g., network, stdin, etc.)
- Monitor program execution and track how tainted data propagates (follow bytes, arithmetic operations, jump addresses, etc.)
- Detect when tainted data is used in dangerous ways

[Papadopoulos’11]

Step 1: Add Taint Checking code

- TaintCheck first runs the code through an emulation environment (Valgrind) and adds instructions to monitor tainted memory.



Dynamic taint analysis

TaintCheck Detection Modules

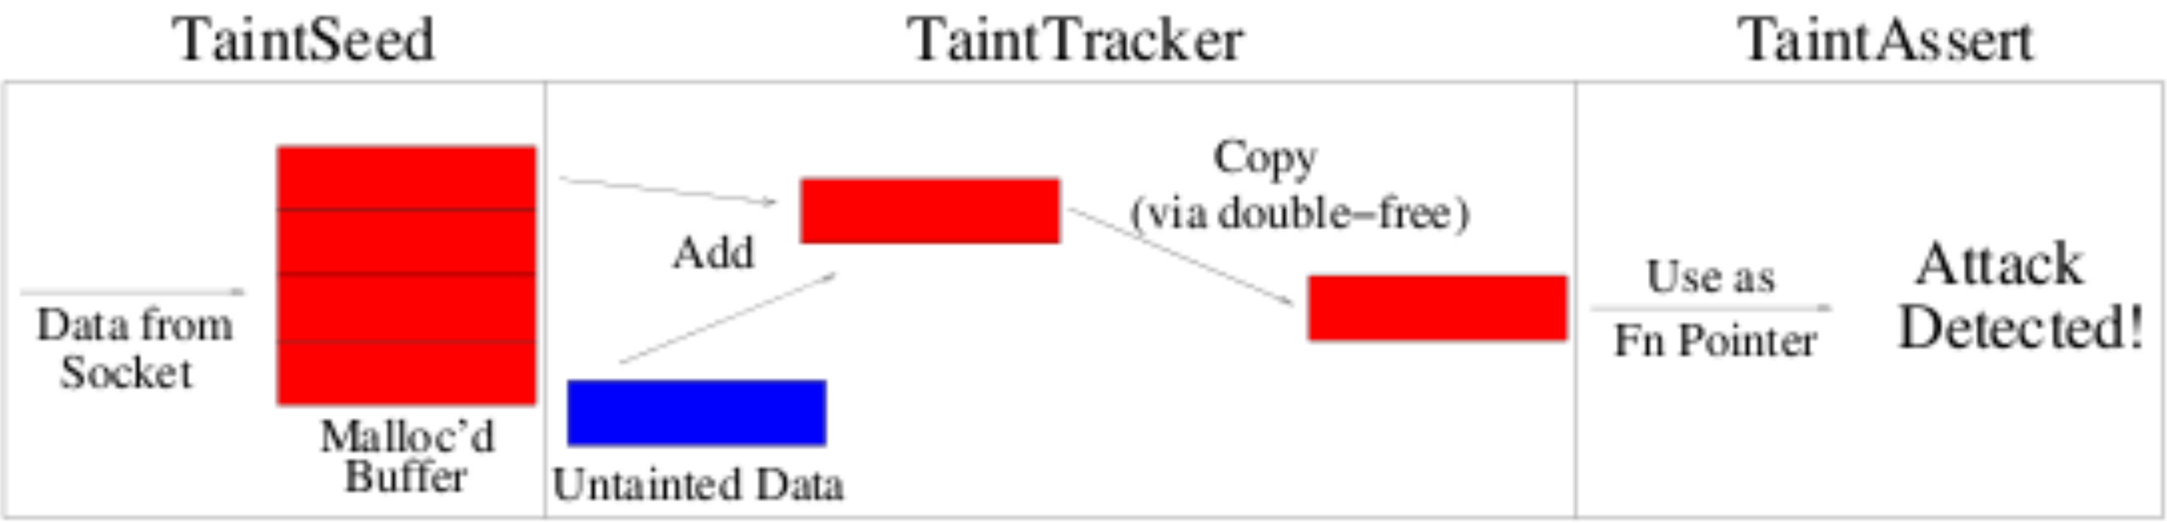


Figure 1. TaintCheck detection of an attack. (Exploit Analyzer not shown).

- TaintSeed: Mark untrusted data as tainted
- TaintTracker: Track each instruction, determine if result is tainted
- TaintAssert: Check is tainted data is used dangerously
  - Jump addresses: function pointers or offsets
  - Format strings: is tainted data used as a format string arg?
  - System call arguments
  - Application or library customized checks

[Papadopoulos'11]

TaintSeed

- Marks any data from untrusted sources as “tainted”
  - Each byte of memory has a four-byte shadow memory that stores a pointer to a Taint data structure if that location is tainted
    - records the system call number, a snapshot of the current stack and a copy of the data that was written.
  - Else store a NULL pointer

Memory is mapped to TDS

[Papadopoulos’11]

TaintTracker

- Tracks each instruction that manipulates data in order to determine whether the result is tainted.
  - When the result of an instruction is tainted by one of the operands, TaintTracker sets the shadow memory of the result to point to the same Taint data structure as the tainted operand.

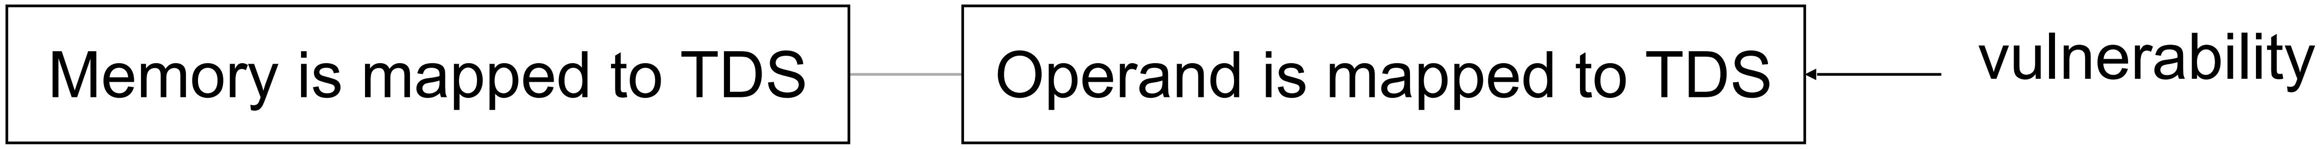
Memory is mapped to TDS

Result is mapped to TDS

[Papadopoulos’11]

TaintAssert

- Checks whether tainted data is used in ways that its policy defines as illegitimate



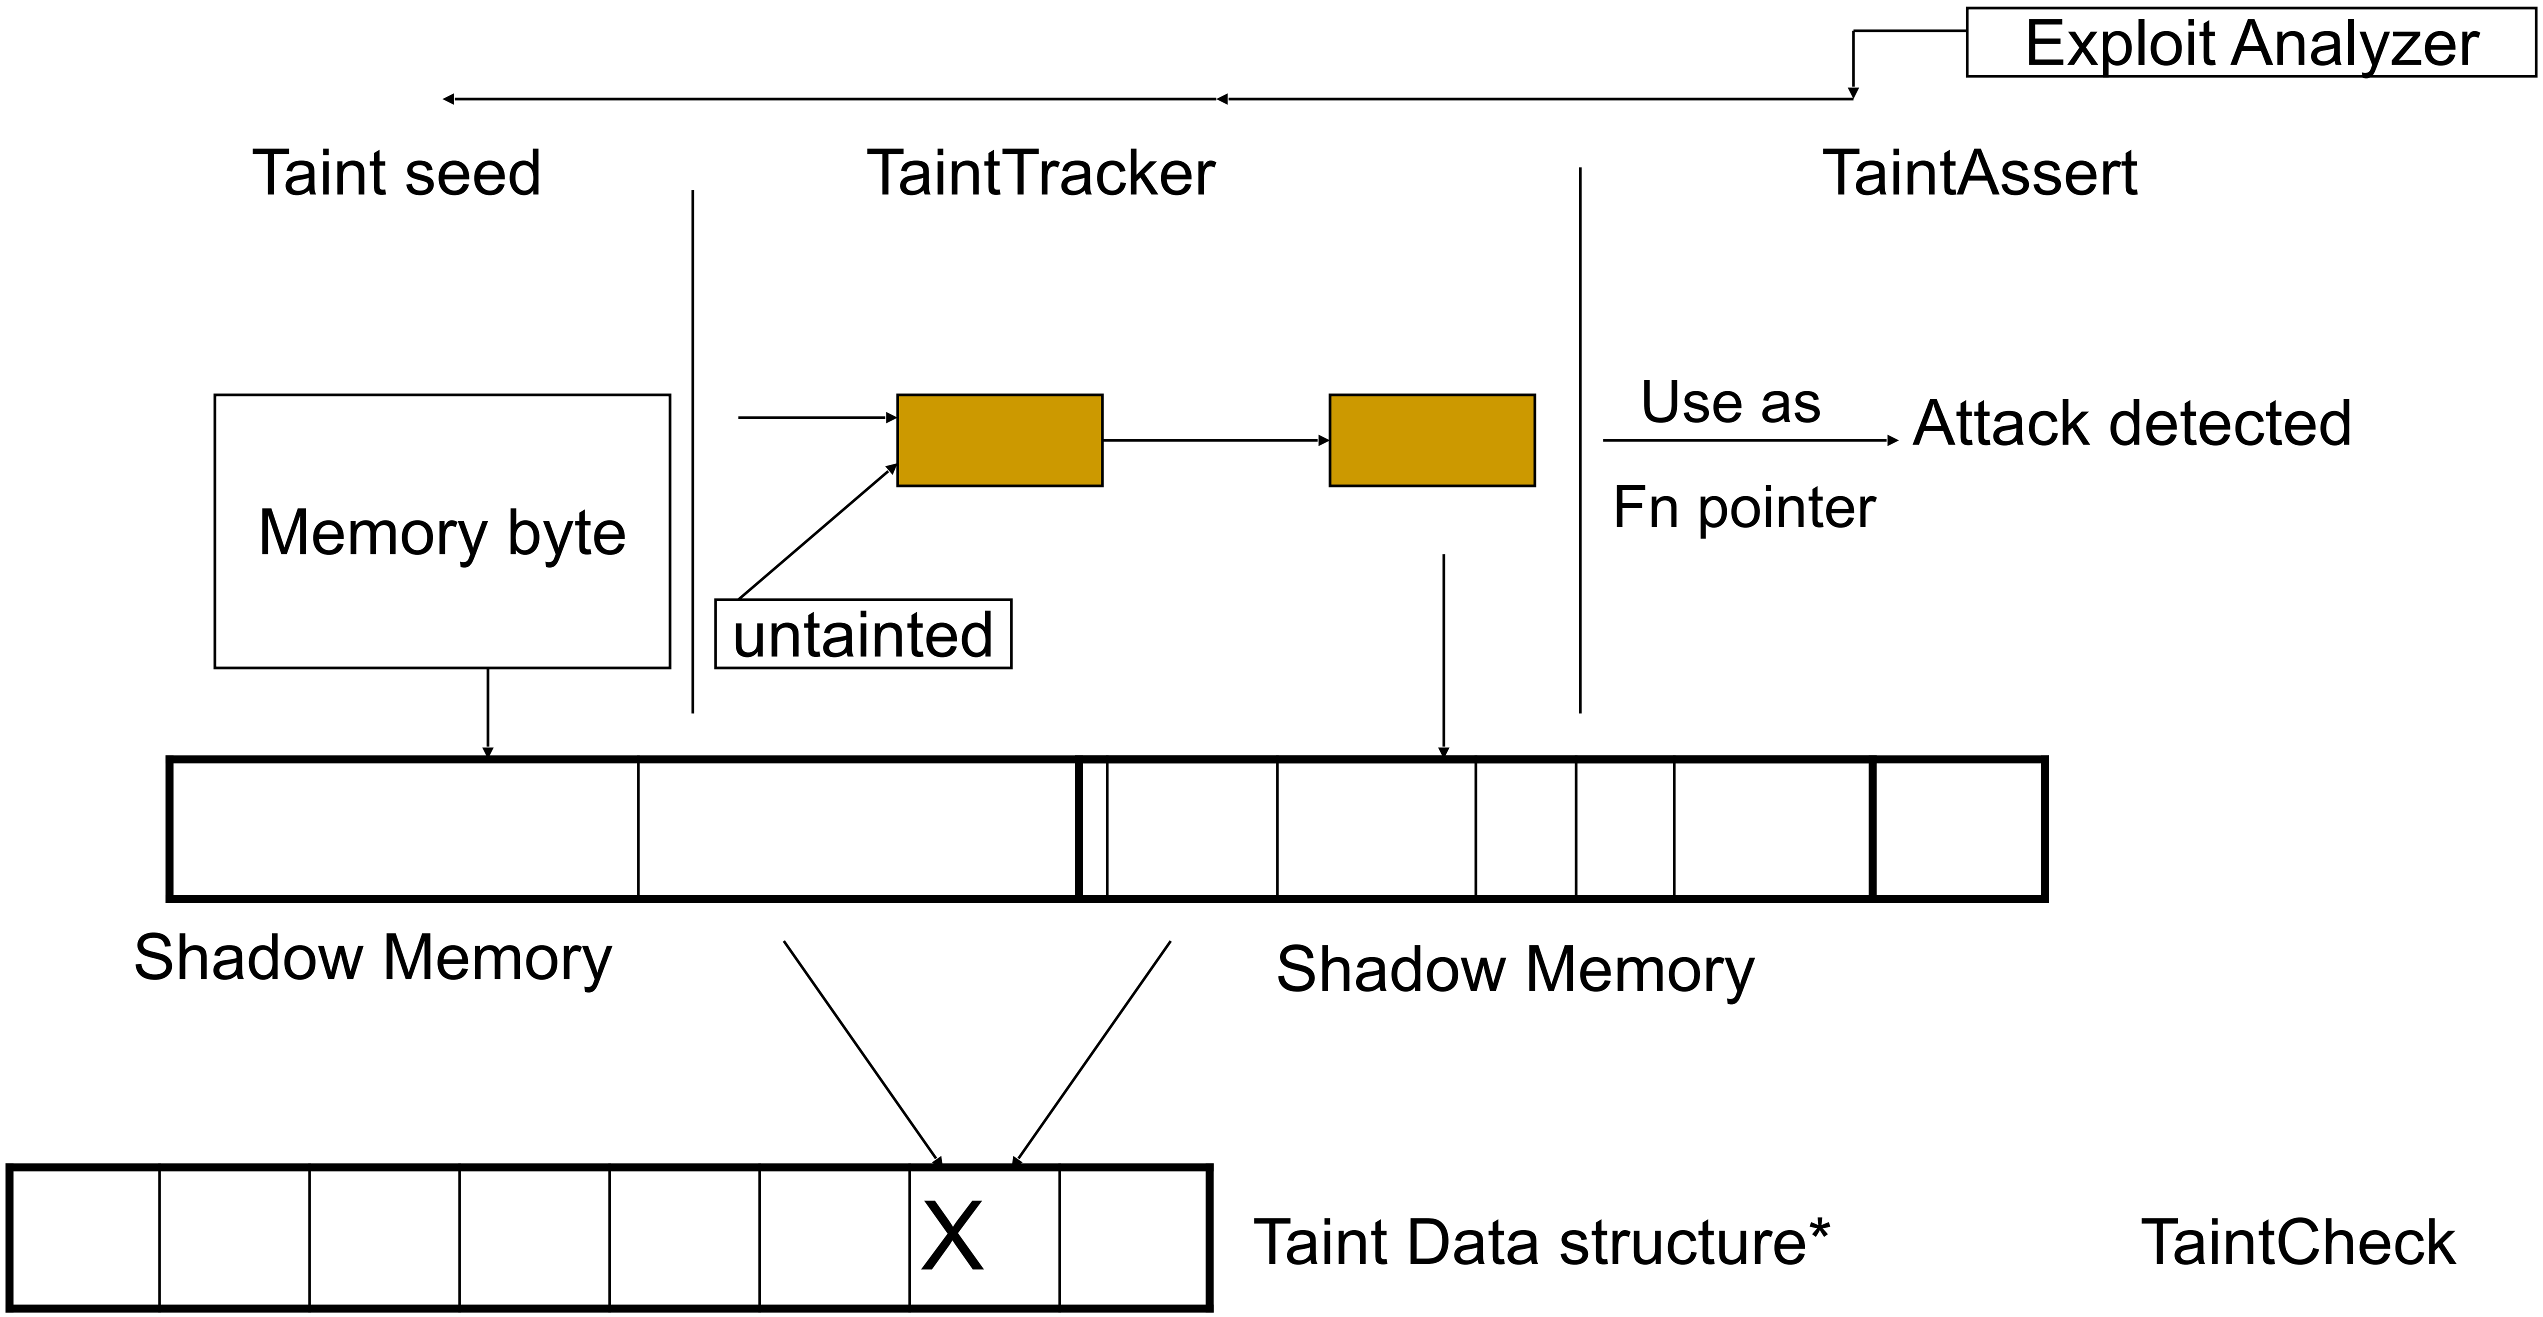
Memory is mapped to TDS

Operand is mapped to TDS

vulnerability

[Papadopoulos’11]

TaintCheck Operation

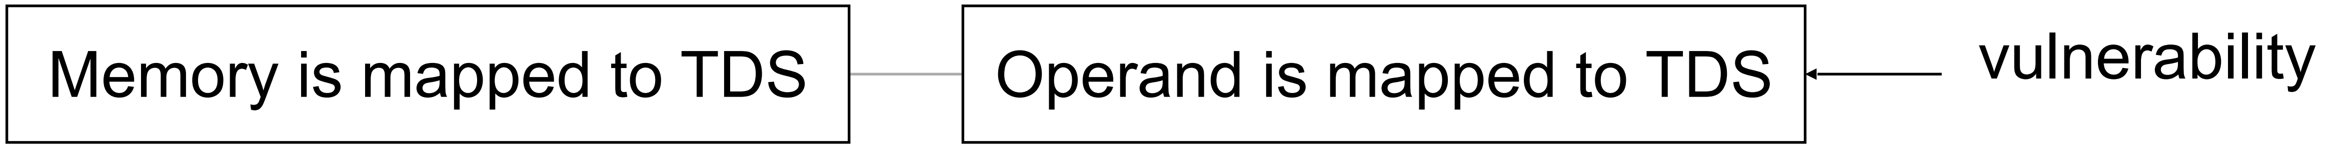


*TDS holds the system call number, a snapshot of the current stack, and a copy of the data that was written

Exploit Analyzer

- Provides useful information about how the exploit happened, and what the exploit attempts to do
- Useful to generate exploit fingerprints

- Usage:
  - Identifying vulnerabilities.
  - Generating exploit signature.



Memory is mapped to TDS

Operand is mapped to TDS

vulnerability

[Papadopoulos’11]

Dynamic Taint Analysis

- Jump addresses:
  - Checks whether tainted data is used as a jump target
  - Instrument before each Ucode jump instruction
- Format strings:
  - Checks whether tainted data is used as format string argument
  - Intercept calls to the printf family of functions
- System call arguments:
  - Checks whether the arguments specified in system calls are tainted
  - Optional policy for execv system call
- Application or library-specific checks:
  - To detect application or library specific attacks

When does TaintCheck Fail?

- A false negative occurs if an attacker can cause sensitive data to take on a value without that data becoming tainted
  - E.g. if (x == 0)y = 0; else if (x == 1) y = 1; ...
- If values are copied from hard-coded literals, rather than arithmetically derived from the input
  - IIS translates ASCII input into Unicode via a table
- If TaintCheck is configured to trust inputs that should not be trusted
  - data from the network could be first written to a file on disk, and then read back into memory

[Papadopoulos’11]

When does TaintCheck give a False Positive?

- TaintCheck detects that tainted data is being used in an illegitimate way even when there is no attack taking place. Possibilities:
    - There are vulnerabilities in the program and need to be fixed, or
    - The program performs sanity checks before using the data

[Papadopoulos’11]

Undertainting

Failing to identify tainted values
- e.g., missing exploits

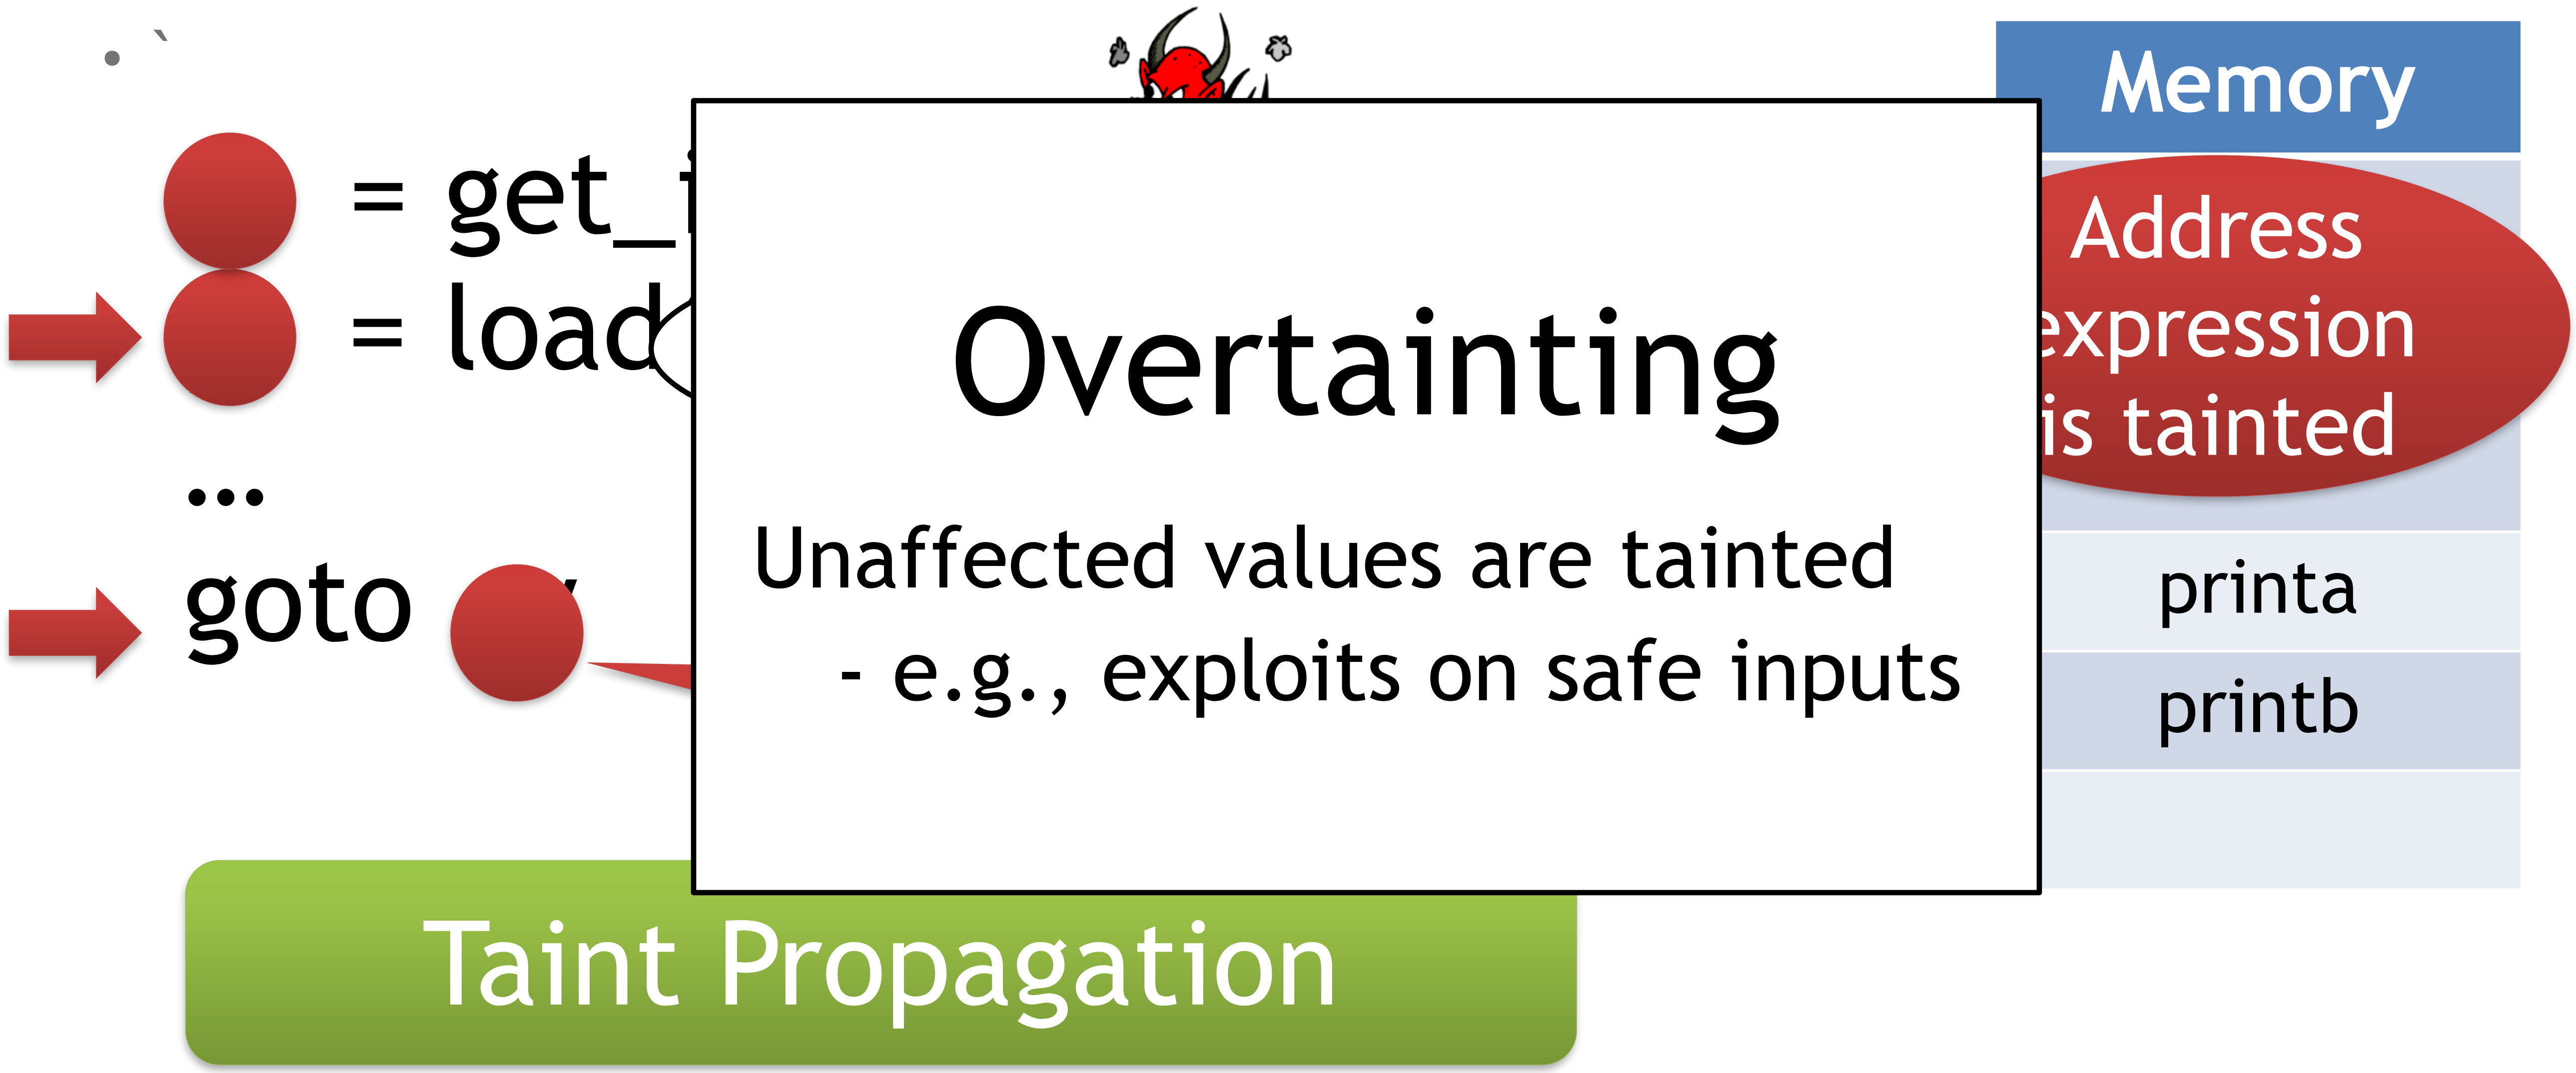
Taint Propagation

τ_μ

Addr	Tainted?
7	F

[Brumley'10]

Policy 2: If either the address or the memory cell is tainted, then the value is tainted



Overtainting

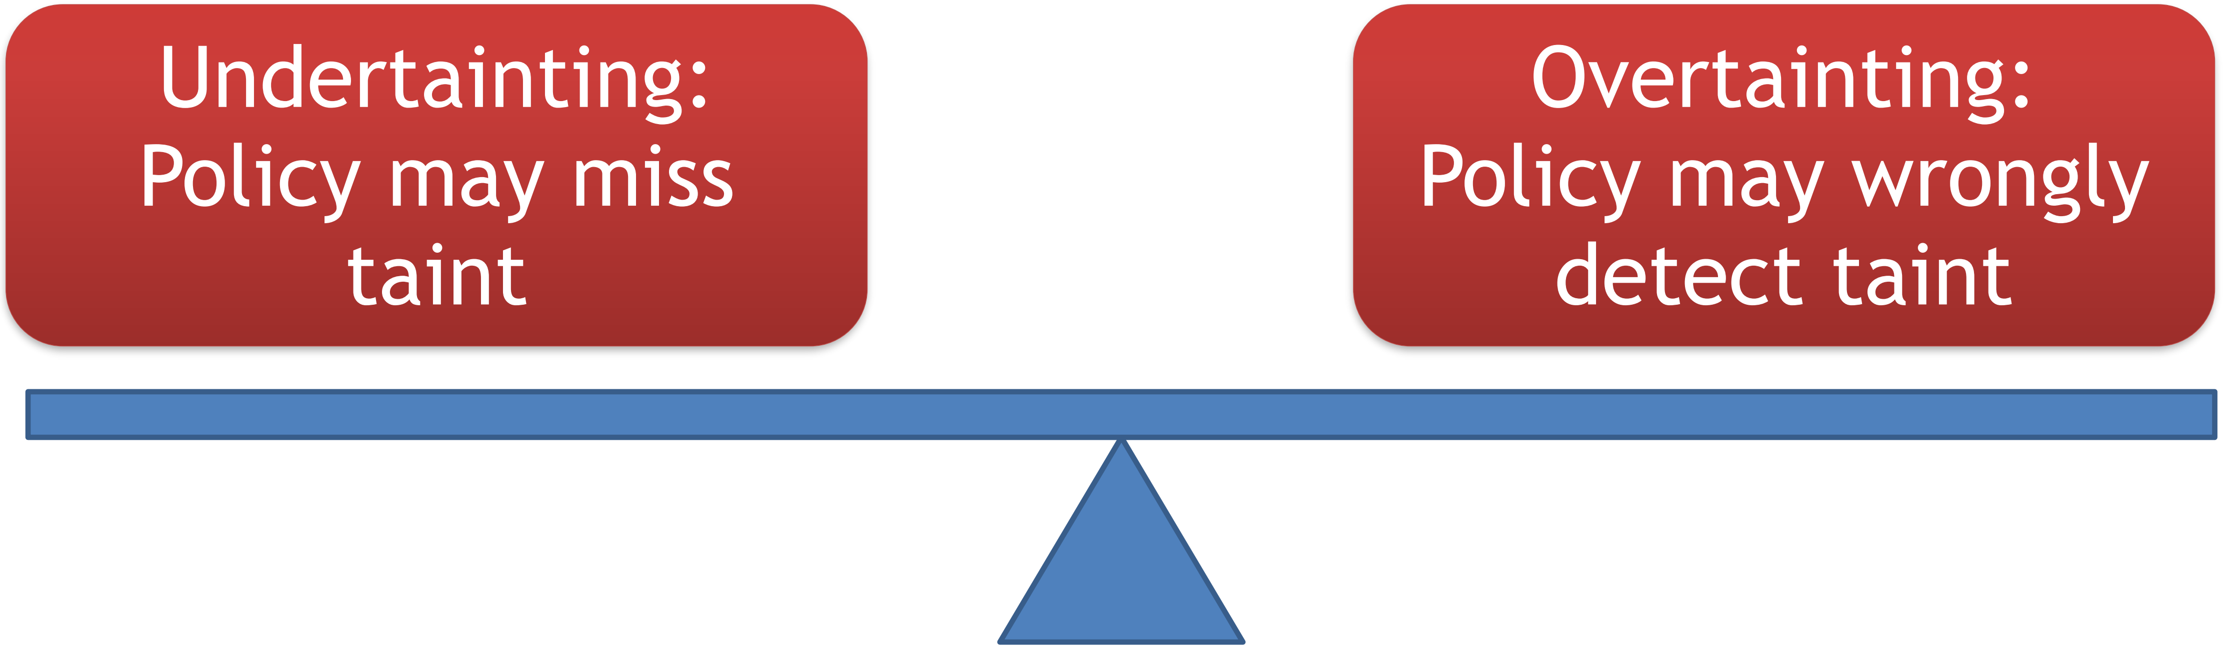
Unaffected values are tainted

- e.g., exploits on safe inputs

[Brumley’10]

General Challenge

- State-of-the-Art is not perfect for all programs



Undertainting: Policy may miss taint

Overtainting: Policy may wrongly detect taint

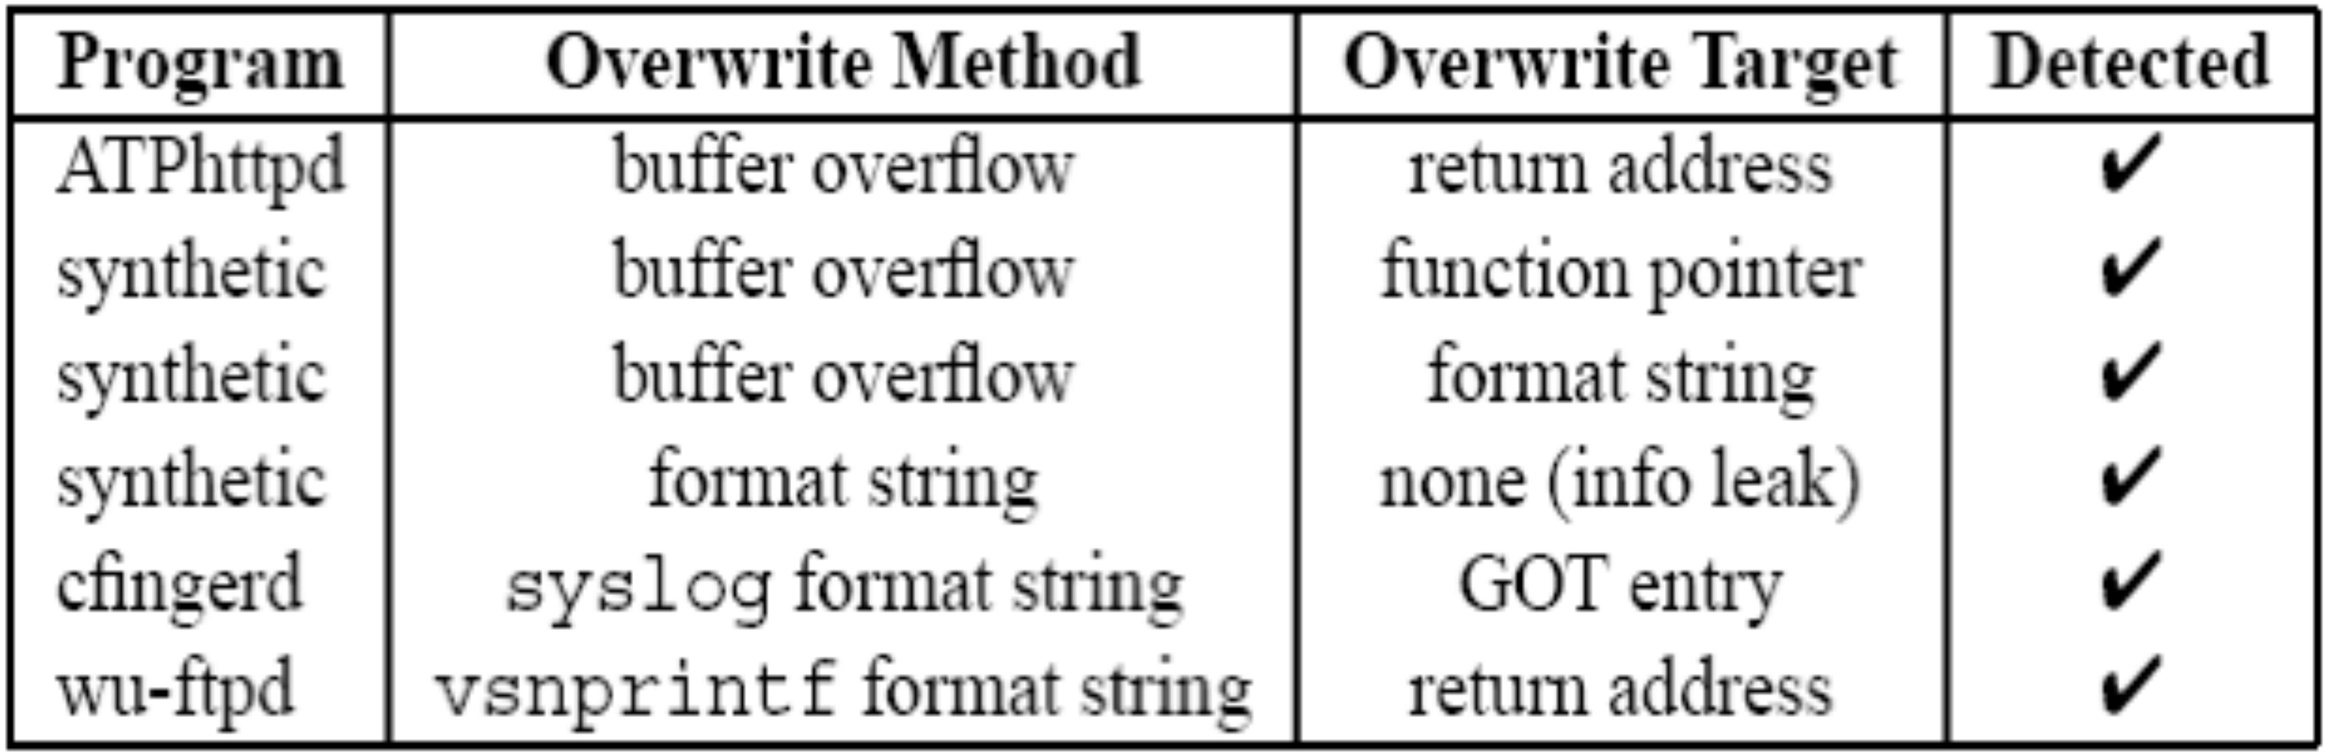
[Brumley’10]

Compatibility with Existing Code

- Does TaintCheck raise false alerts?
- Networked programs: 158K+ DNS queries
  - No false +ves
- All (!!) client and non-network programs (tainted data is stdin):
  - Only vim and firebird caused false +ves (data from config files used as offset to jump address)

[Papadopoulos'11]

Attack Detection: Synthetic + Actual Exploits



Program	Overwrite Method	Overwrite Target	Detected
ATPhttpd	buffer overflow	return address	✔
synthetic	buffer overflow	function pointer	✔
synthetic	buffer overflow	format string	✔
synthetic	format string	none (info leak)	✔
cfingerd	`syslog` format string	GOT entry	✔
wu-ftpd	`vsnprintf` format string	return address	✔

[Papadopoulos'11]

Evaluation - Evaluation of attack detection

- Synthetic exploits
    - They wrote small programs for:

Return Address	Function Pointer	Format String
“gets” for long input	Same	Line input from user
Overwrote the stack – overwrote return address	Overwrote the stack – overwrote function pointer	Overwrote format string
Attack detected as return addr was tainted from user input	Attack detected as func pointer was tainted from user input	TaintCheck determined correctly when the format string was tainted

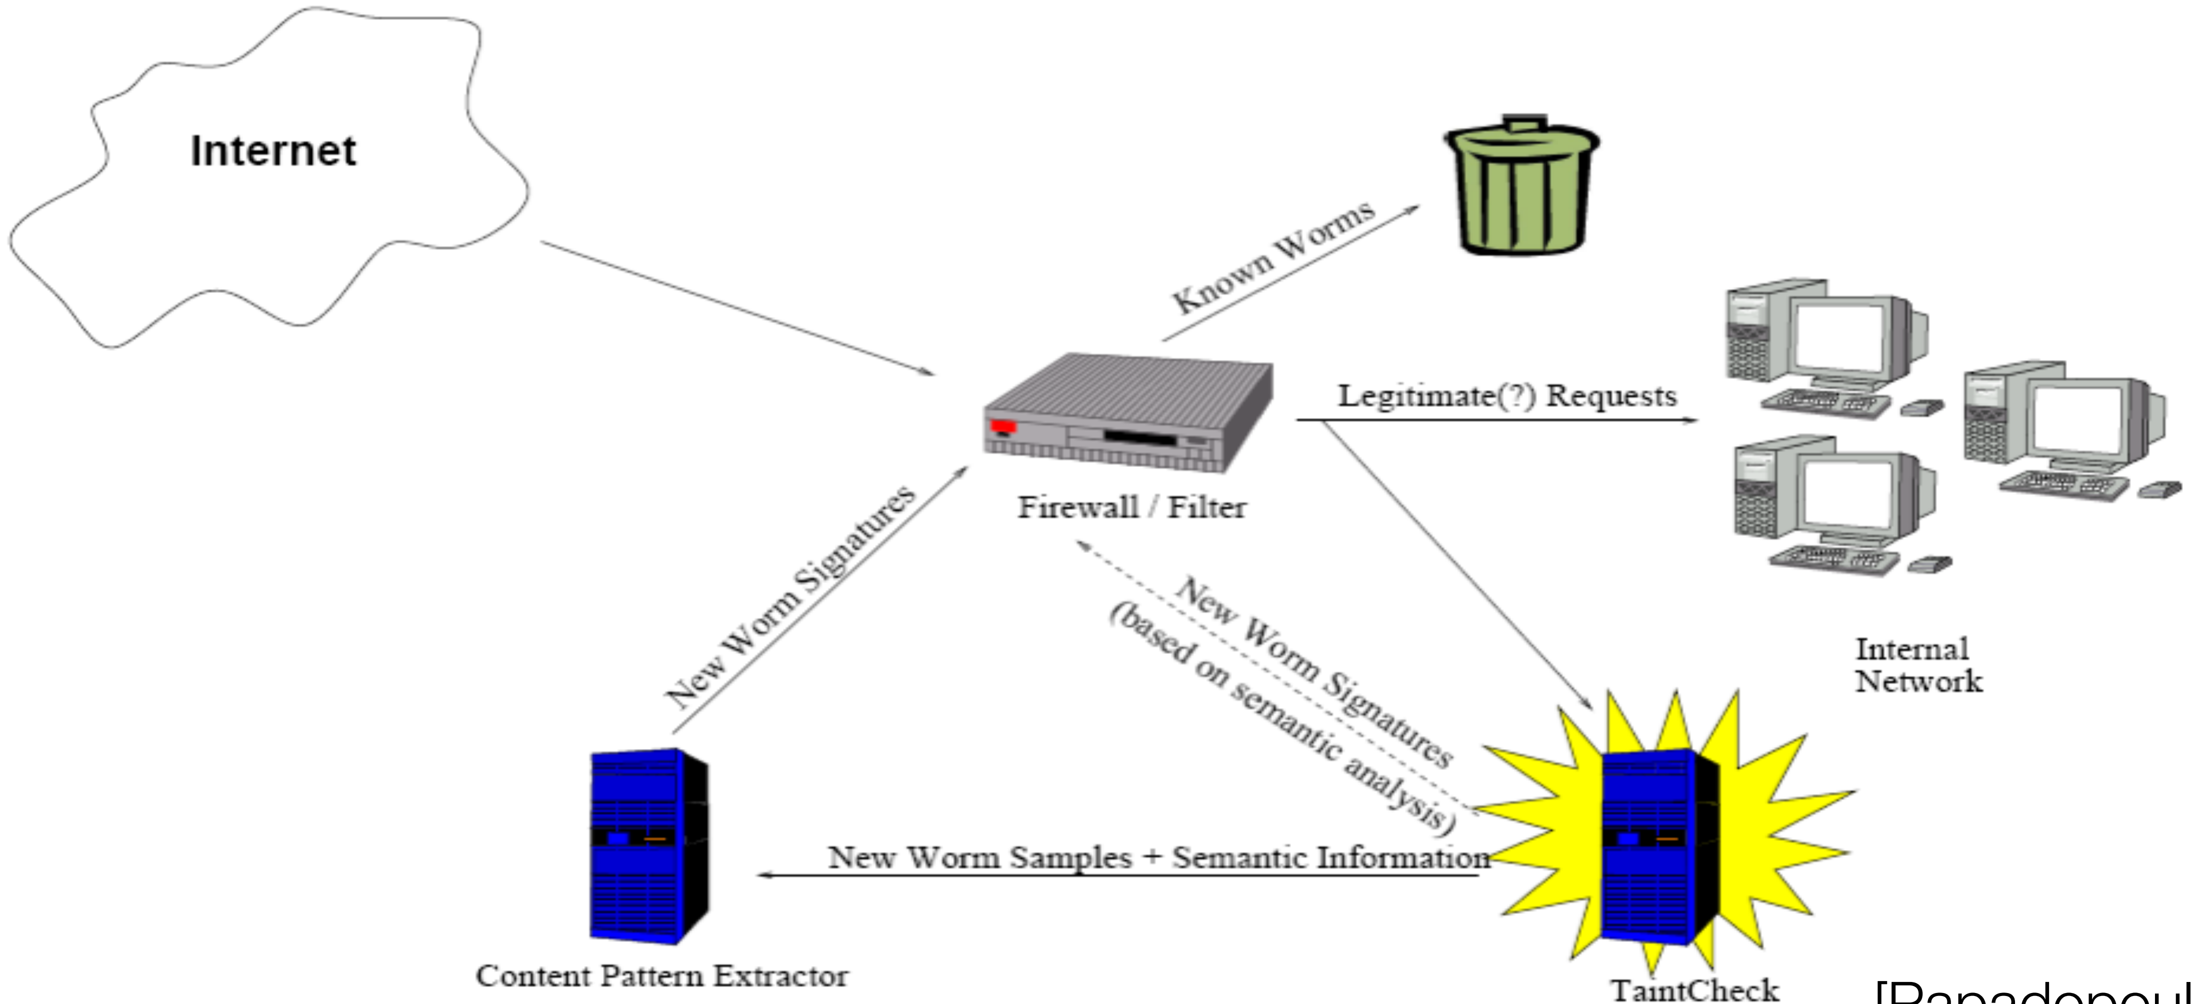
Evaluation - Evaluation of attack detection

- Actual exploits: TaintCheck evaluated on exploits to three vulnerable servers: a web server, a finger daemon, and an FTP server.

ATPhttpd exploit	cfingerd exploit	wu-ftpd exploit
Web server program	Finger daemon	ftp
Ver 0.4b and lower are vulnerable to buffer overflow	Ver 1.4.2 and lower are vulnerable to format string	Version 2.6.0 of wu-ftpd has a format string vulnerability in a call to vsnprintf.
malicious GET request with a very long file name (shellcode and a return address) was sent to server. Return address overwritten so when func retruns it jumps to shell code inside the file name -> remote shell for attacker	When prompts for a user name, exploit responds with a string beginning with "version" + malicious code - cfingerd copies the whole string into memory, but only reads to the end of the string "version". Malicious code in memory starts working	Format string to overwrite the return address was detected
TaintCheck detected return addr was tainted and identified the new value	Detected also	TaintCheck successfully detects both that the format string supplied to vsnprintf is tainted, and that the overwritten return address is tainted.

Automatic Signature Generation

- Automatic semantic analysis based signature generation
  - Find value used to override return address – typically fixed value in the exploit code
  - Sometimes as little as 3 bytes! See paper for details



[Papadopoulos’11]

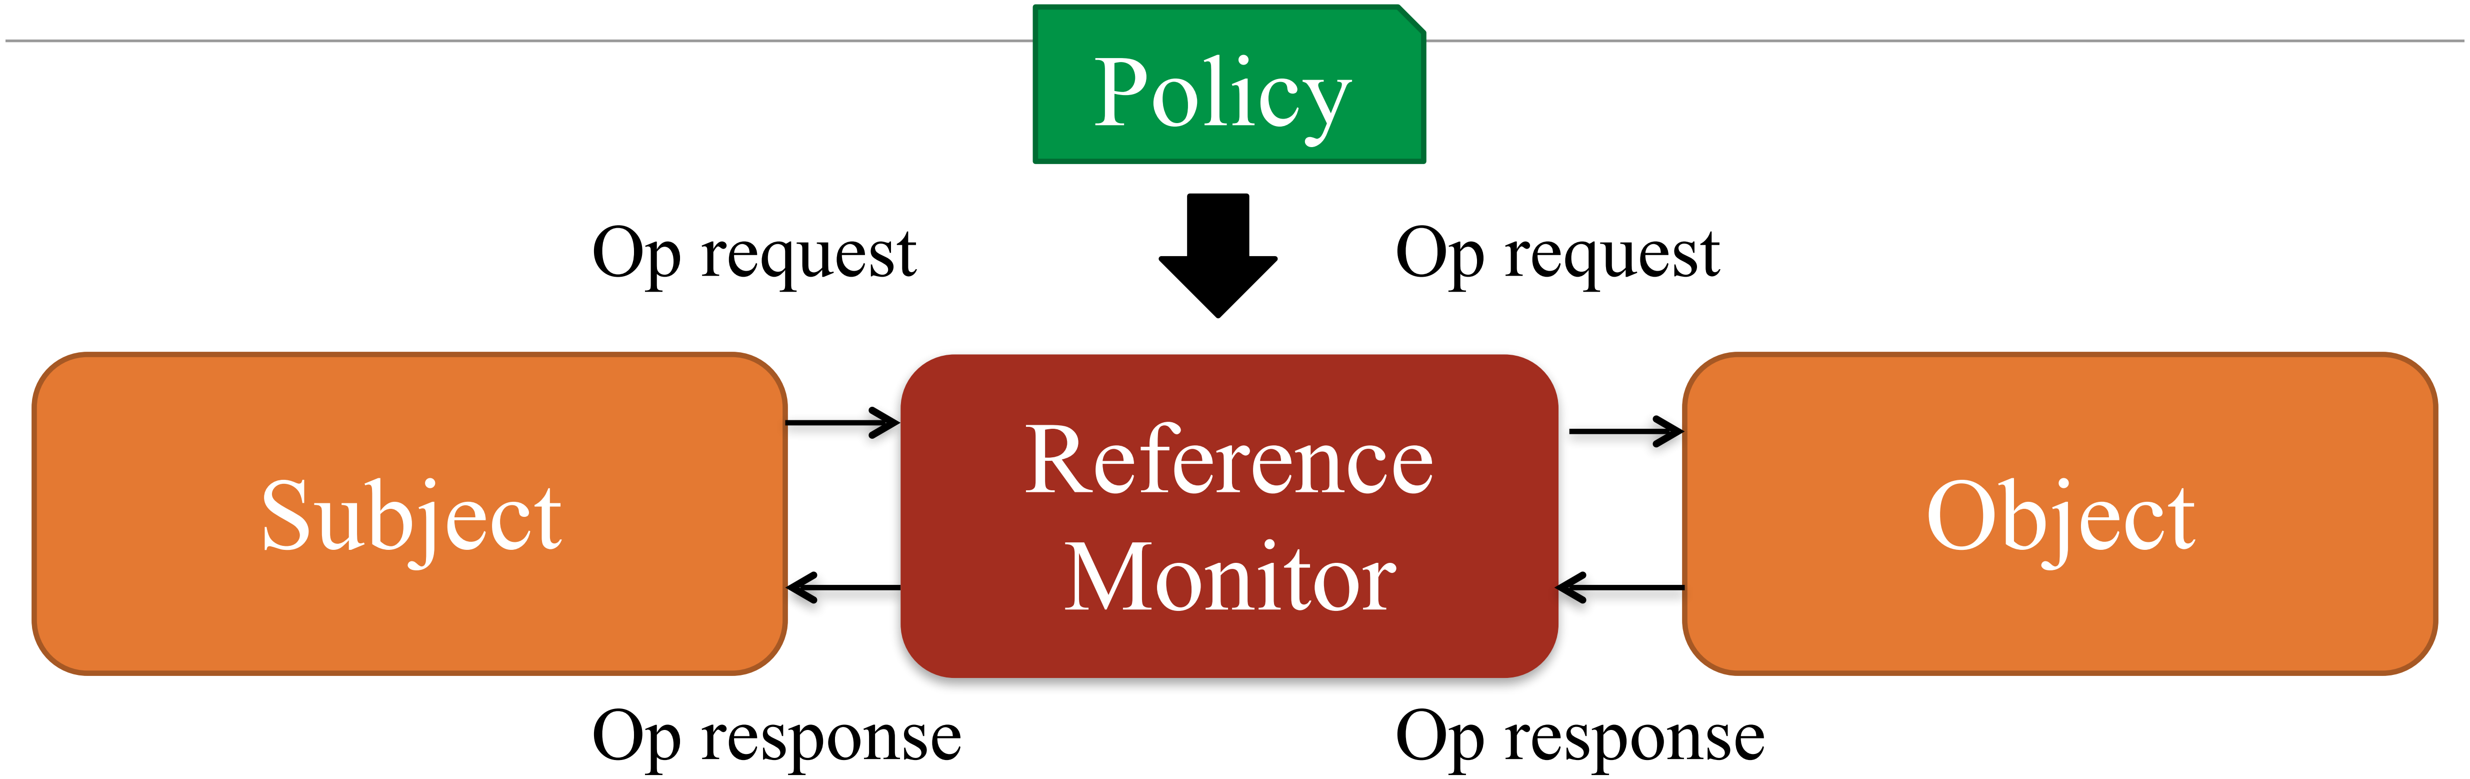
[Brumley'15]

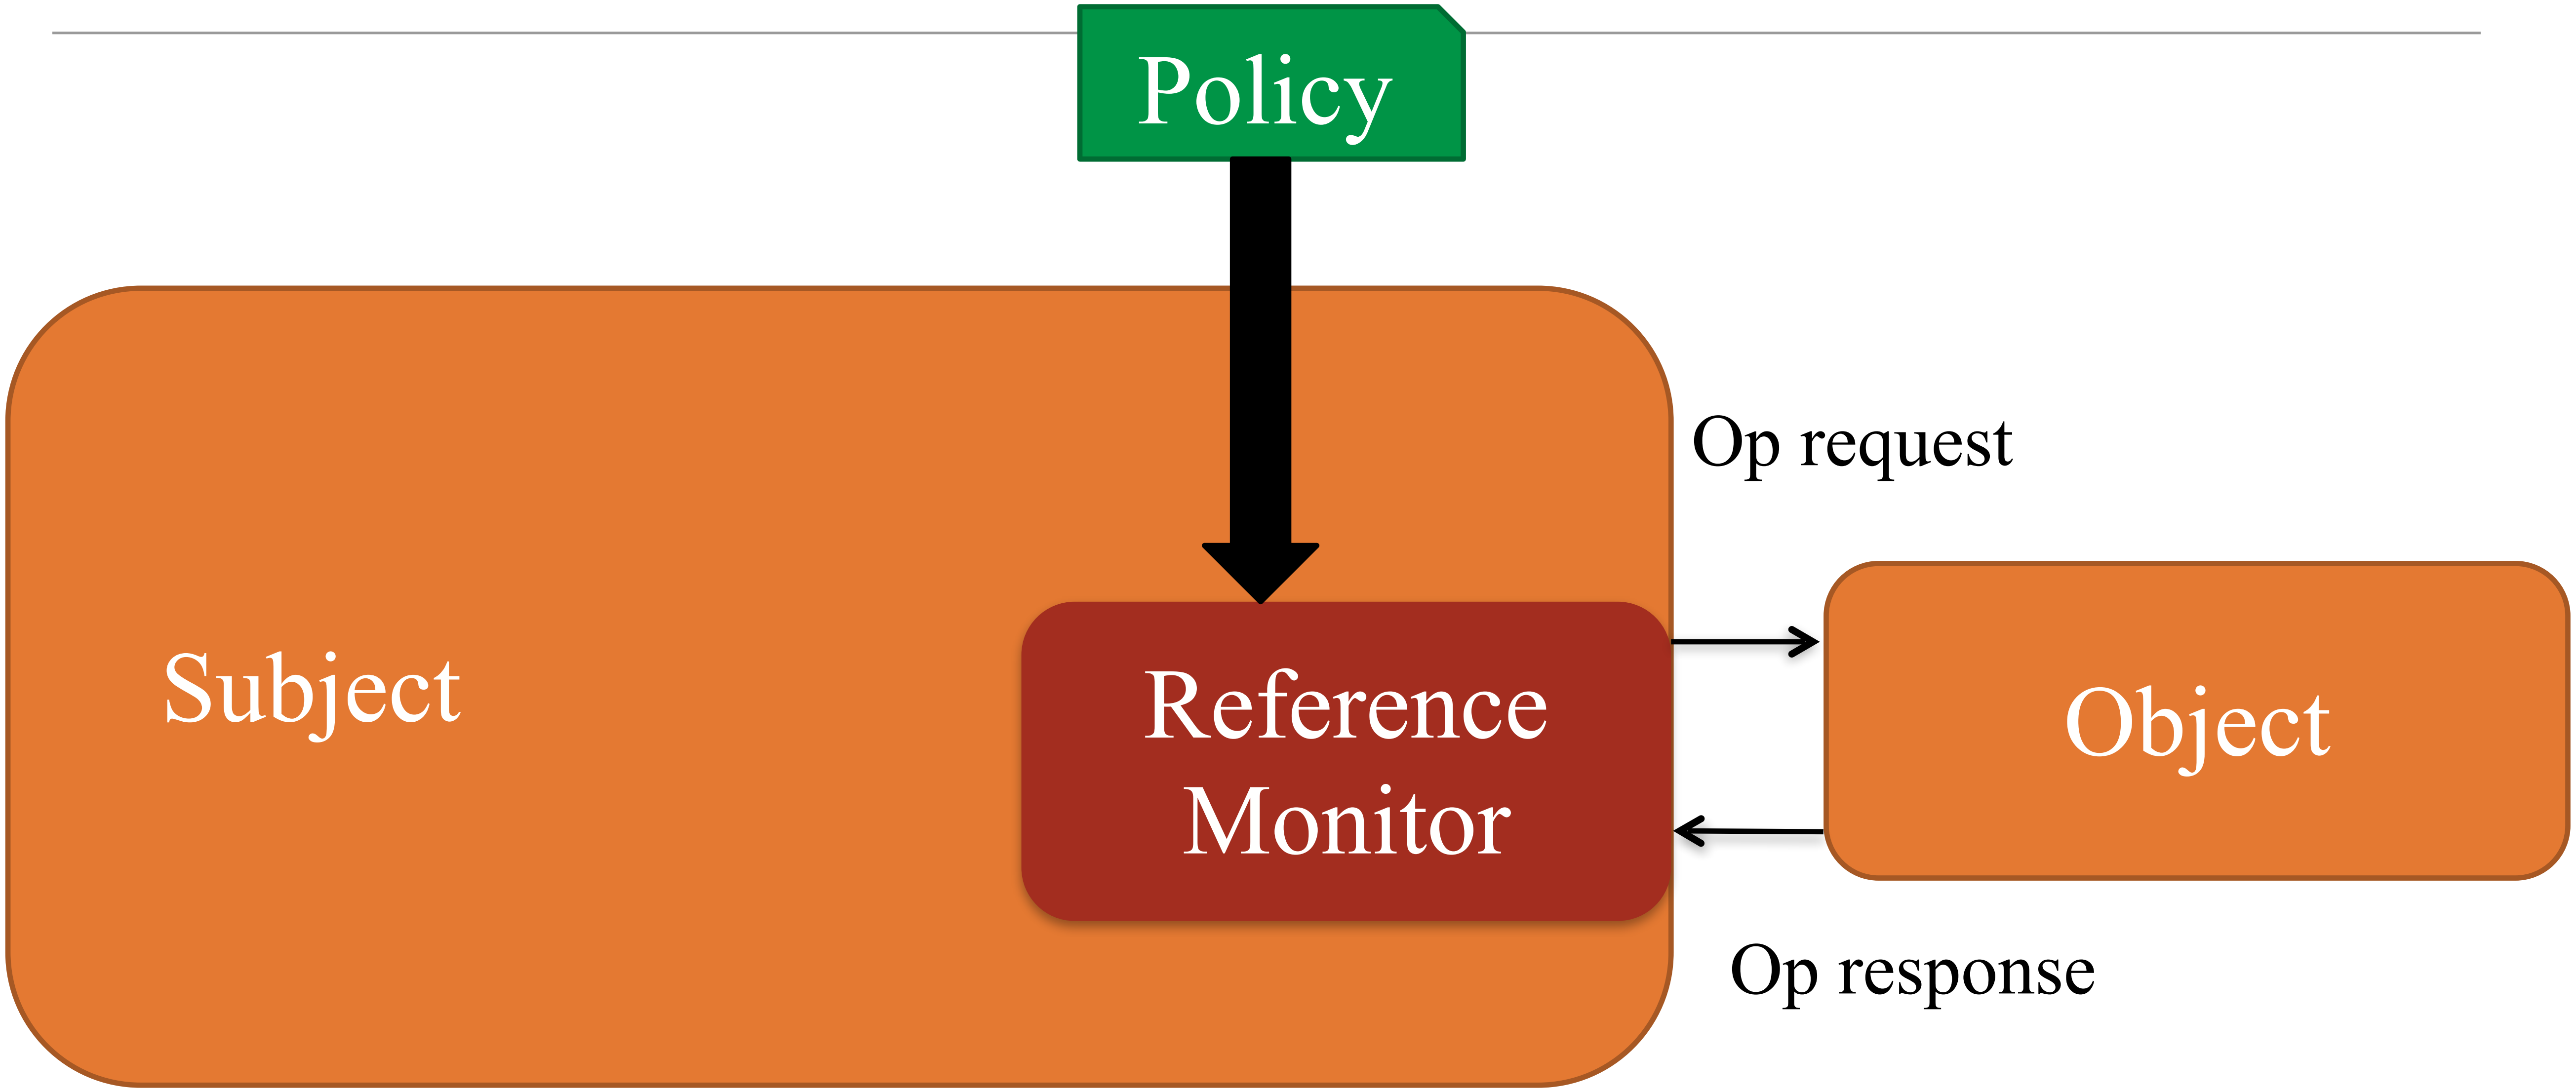
Reference Monitor: Principles



- **Complete Mediation:** The reference monitor must always be invoked
- **Tamper-proof:** The reference monitor cannot be changed by unauthorized subjects or objects
- **Verifiable:** The reference monitor is small enough to thoroughly understand, test, and ultimately, verify.

[Brumley'15]

Inlined Referenced Monitor



Today's Example:
Inlining a control flow policy into a program

Control-Flow Integrity: Principles, Implementations, and Applications

Martin Abadi, Mihai Budiu, U´lfar Erlingsson, Jay Ligatti, CCS 2005

Control Flow Integrity

- protects against powerful adversary
  - with full control over entire data memory
- widely-applicable
  - language-neutral; requires binary only
- provably-correct & trustworthy
  - formal semantics; small verifier
- efficient
  - hmm… 0-45% in experiments; average 16%

[Brumley’15]

CFI Adversary Model

Can

- Overwrite any data memory at any time
  - stack, heap, data segs
- Overwrite registers in current context

Can Not

- Execute Data
  - NX takes care of that
- Modify Code
  - text seg usually read-only
- Write to %ip
  - true in x86
- Overwrite registers in other contexts
  - kernel will restore regs

[Brumley'15]

CFI Overview

- Invariant: Execution must follow a path in a control flow graph (CFG) created ahead of run time.

“static”

- Method:
  - build CFG statically, e.g., at compile time
  - instrument (rewrite) binary, e.g., at install time
    - add IDs and ID checks; maintain ID uniqueness
  - verify CFI instrumentation at load time
    - direct jump targets, presence of IDs and ID checks, ID uniqueness
  - perform ID checks at run time
    - indirect jumps have matching IDs

[Brumley’15]

Control Flow Graphs

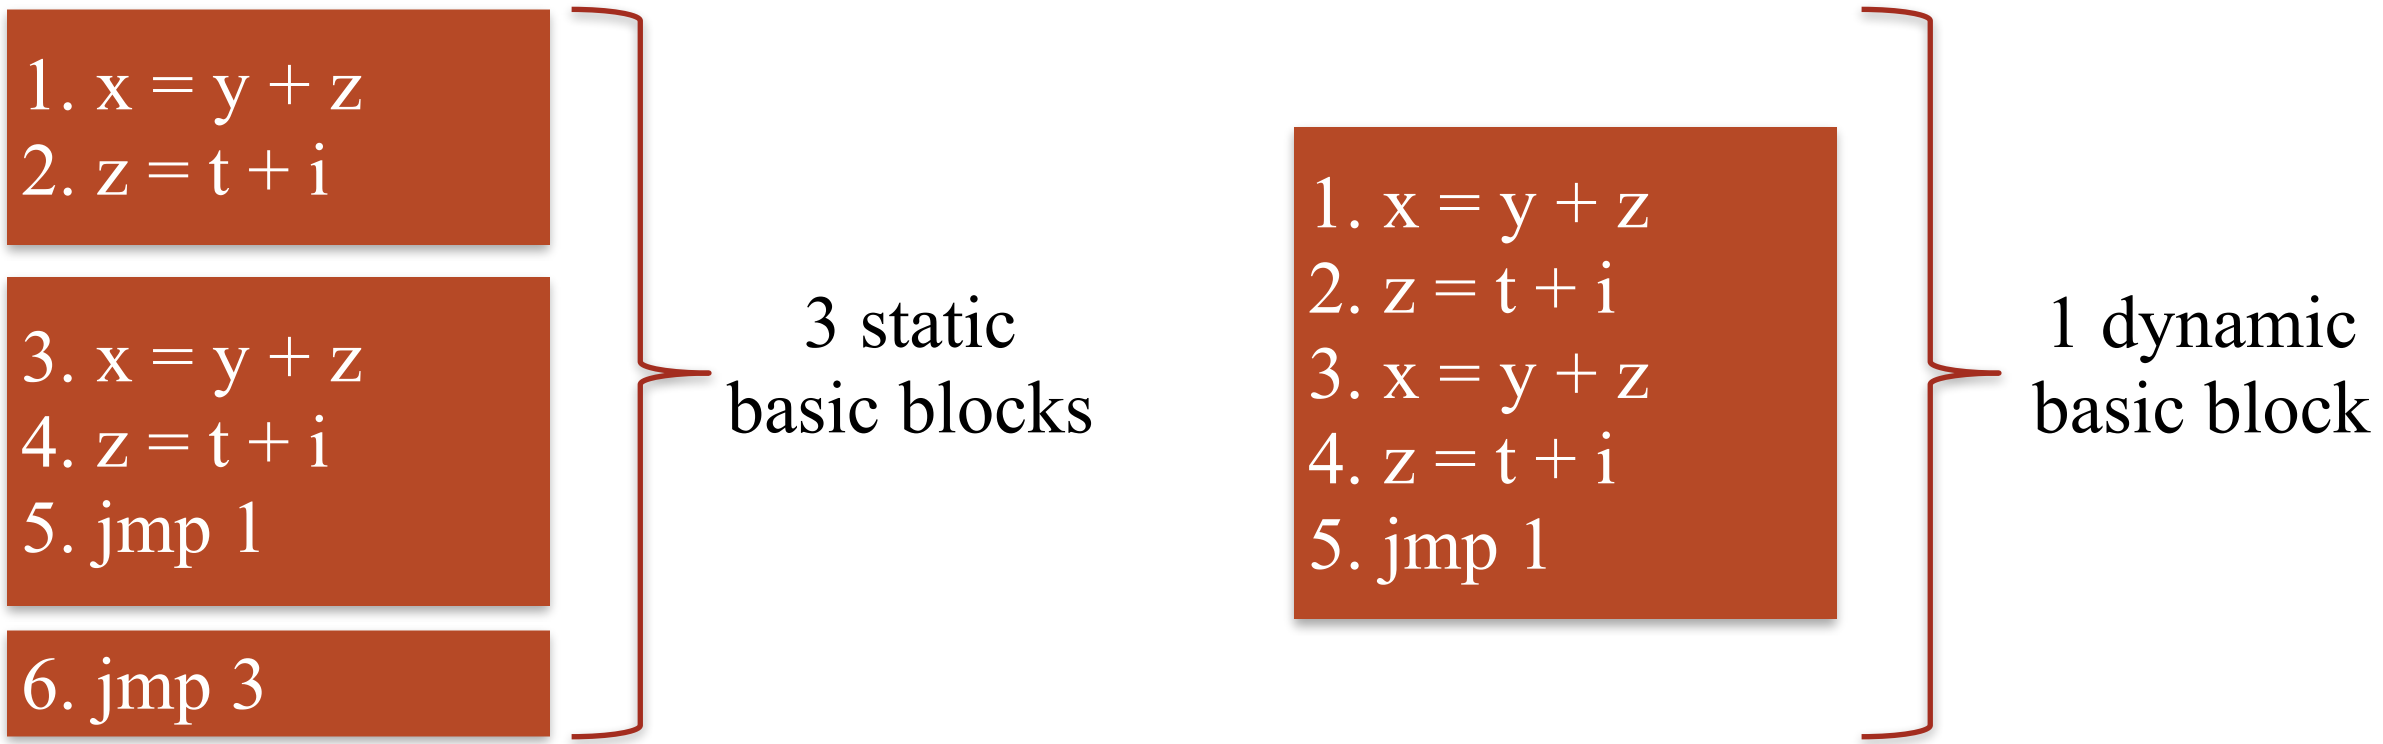
[Brumley’15]

Basic Block

- D

control is "straight"
(no jump targets except at the beginning,
no jumps except at the end)

no outside instruction can execute between two instructions in the sequence



1. x = y + z
2. z = t + i

3. x = y + z
4. z = t + i
5. jmp 1

6. jmp 3

3 static
basic blocks

1. x = y + z
2. z = t + i
3. x = y + z
4. z = t + i
5. jmp 1

1 dynamic
basic block

[Brumley'15]

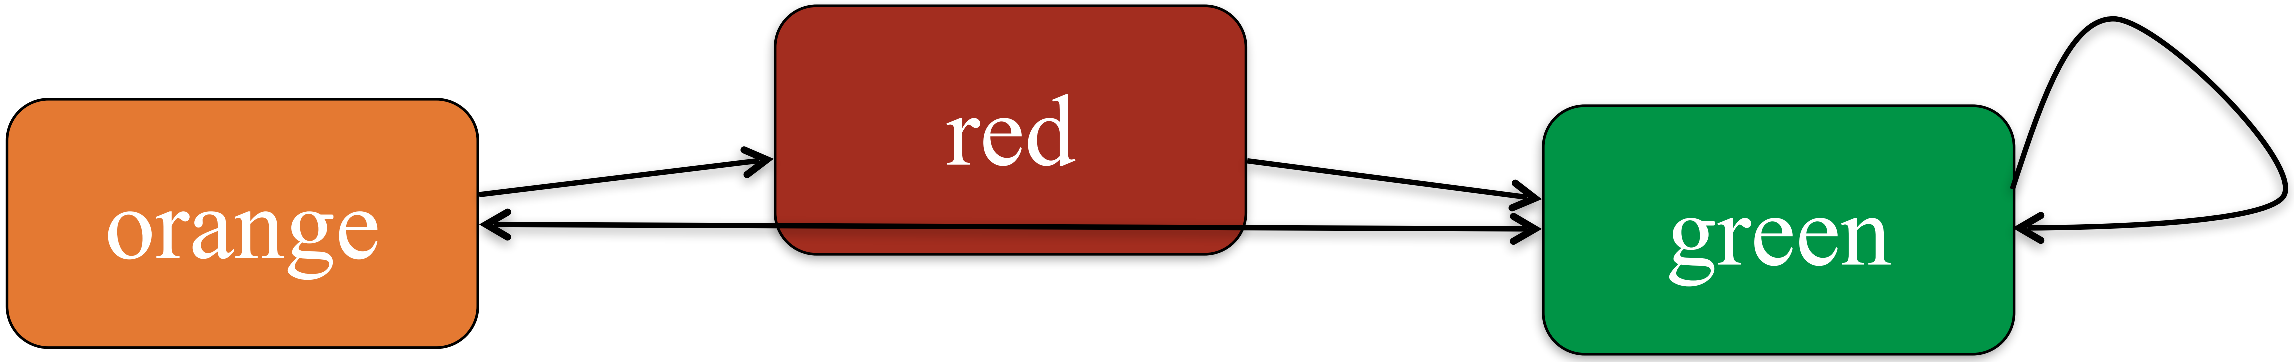
CFG Definition

- A static Control Flow Graph is a graph where
  - each vertex v_i is a basic block, and
  - there is an edge (v_i, v_j) if there may be a transfer of control from block v_i to block v_j.
- Historically, the scope of a “CFG” is limited to a function or procedure, i.e., intra-procedural.

Call Graph

- Nodes are functions. There is an edge (v_i, v_j) if function v_i calls function v_j.

```
void orange()    void red(int x)     void green()
{                {                   {
1. red(1);       green();              green();
2. red(2);       ...                   orange();
3. green();      }                   }
}
```



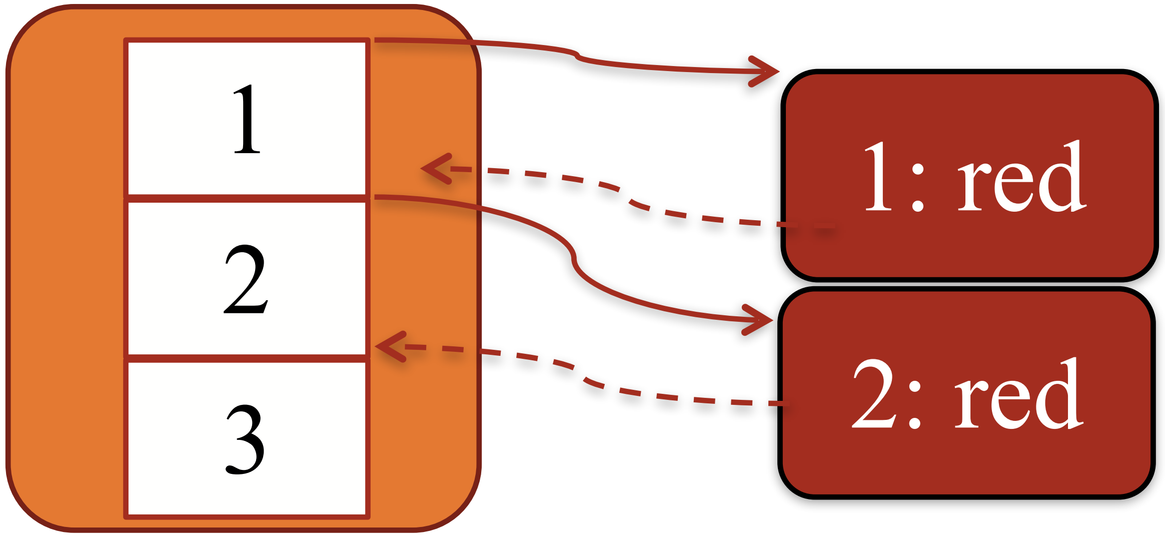
Super Graph

- Superimpose CFGs of all procedures over the call graph

```
void orange()
{
1. red(1);
2. red(2);
3. green();
}
```

```
void red(int x)
{
..
}
```

```
void green()
{
  green();
  orange();
}
```



A *context sensitive* super-graph for orange lines 1 and 2.

Precision: Sensitive or Insensitive

- The more precise the analysis, the more accurate it reflects the “real” program behavior.
    - More precise = more time to compute
    - More precise = more space
    - Limited by soundness/completeness tradeoff

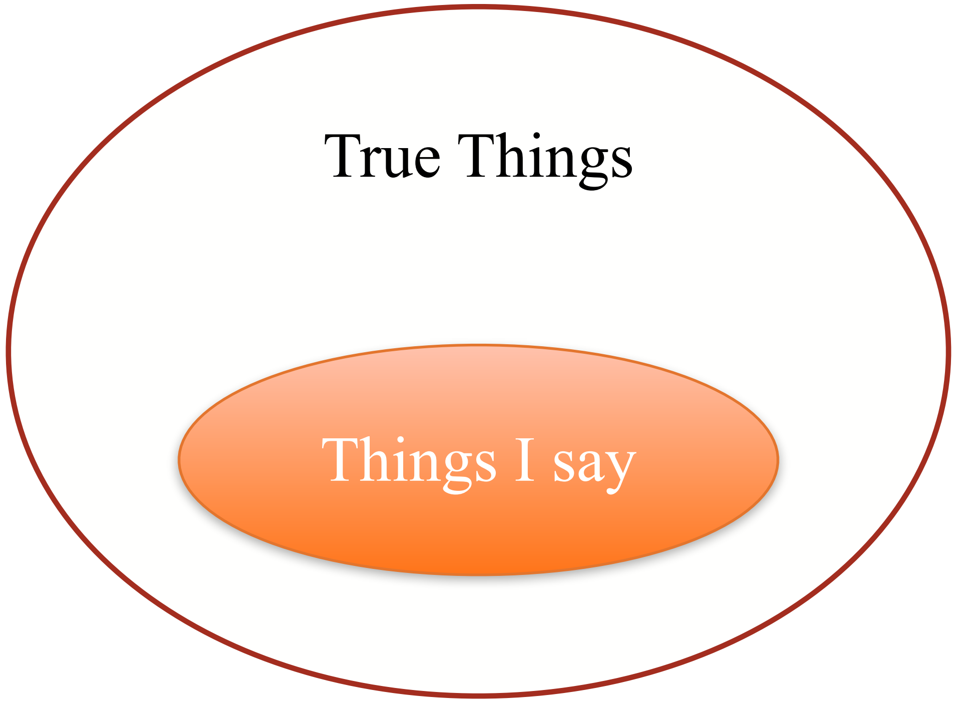
- Common Terminology in any Static Analysis:
    - Context sensitive vs. context insensitive
    - Flow sensitive vs. flow insensitive
    - Path sensitive vs. path insensitive

[Brumley’15]

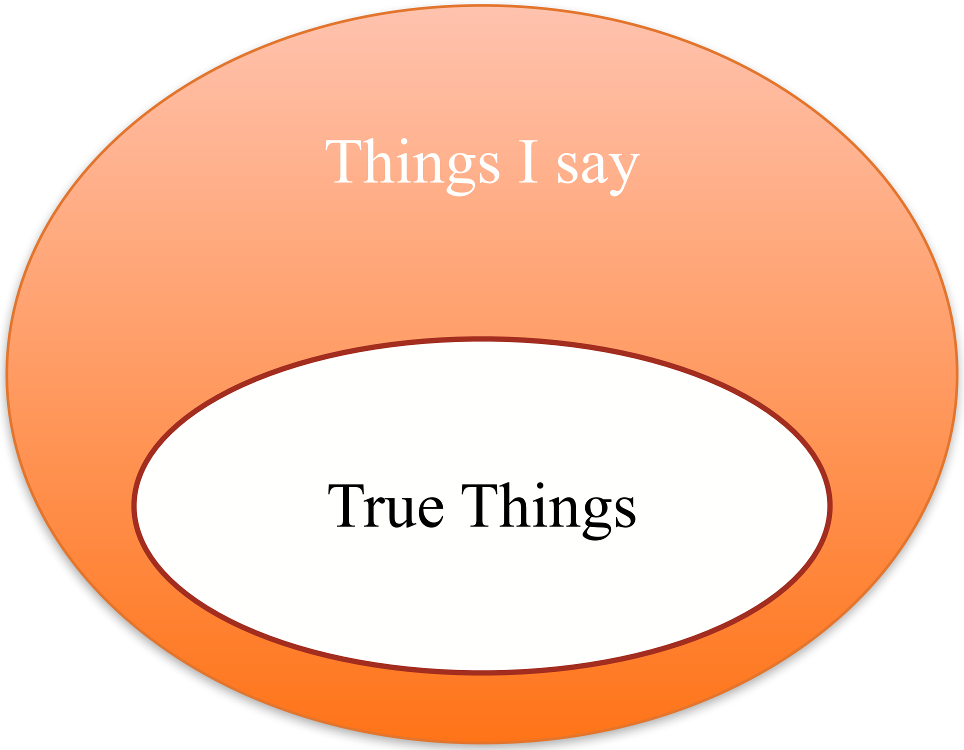
Soundness Completeness

If analysis says X is true, then X is true.

If X is true, then analysis says X is true.



Trivially Sound: Say nothing



Trivially complete: Say everything

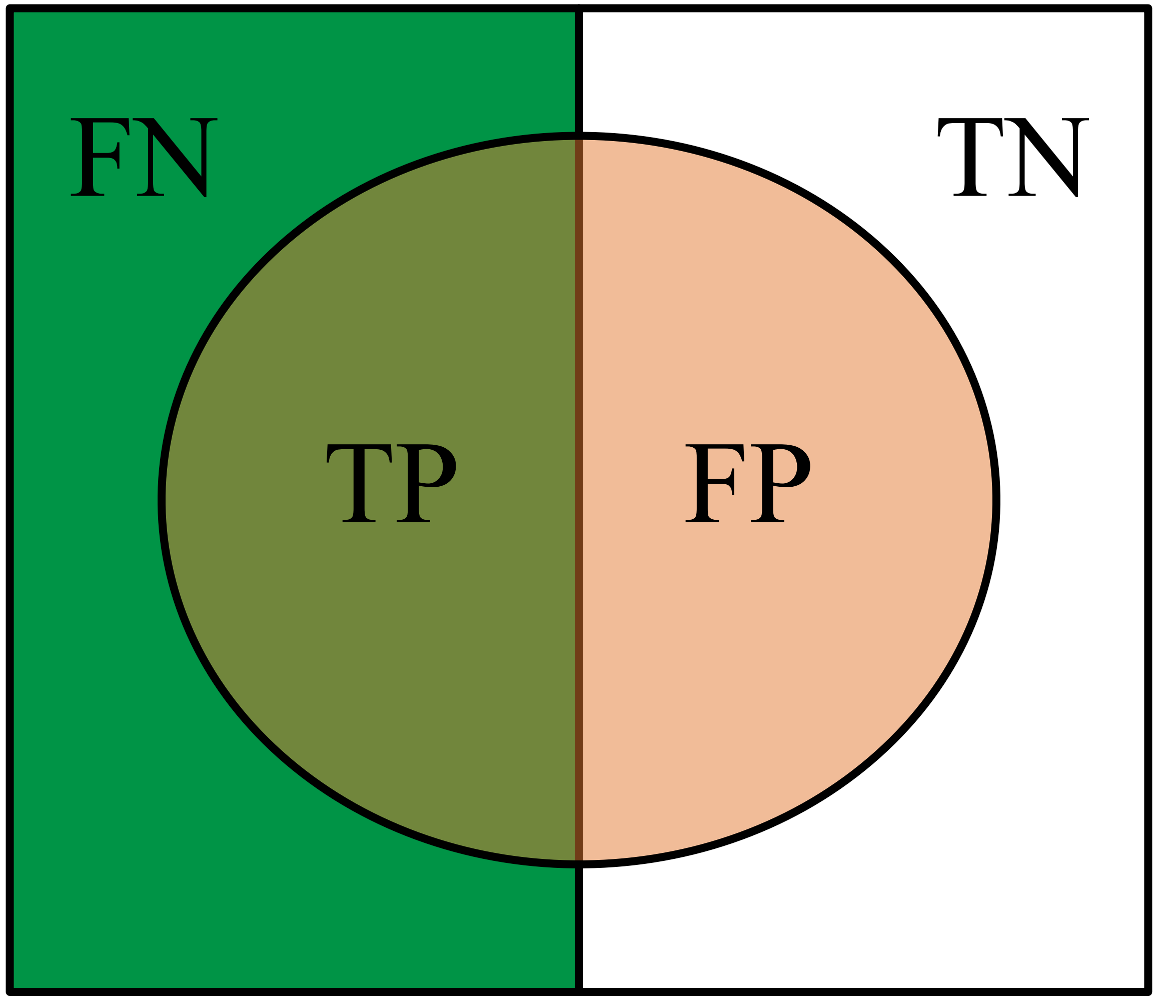
Sound and Complete: Say exactly the set of true things!

Soundness, Completeness, Precision, Recall, False Negative, False Positive, All that Jazz…

Imagine we are building a *classifier*.

Ground truth: things on the left is "in".

Our classifier: things inside circle is "in".



Sound means FP is empty

Complete means FN is empty

Precision = TP/(TP+FP)

Recall = TP/(FN+TP)

False Positive Rate = FP/(TP+FP)

False Negative Rate = FN/(FN+TN)

Accuracy = (TP+TN)/(Σ everything)

Context Sensitive

Whether different calling contexts are distinguished

```
void yellow()
{
1. red(1);
2. red(2);
3. green();
}
```

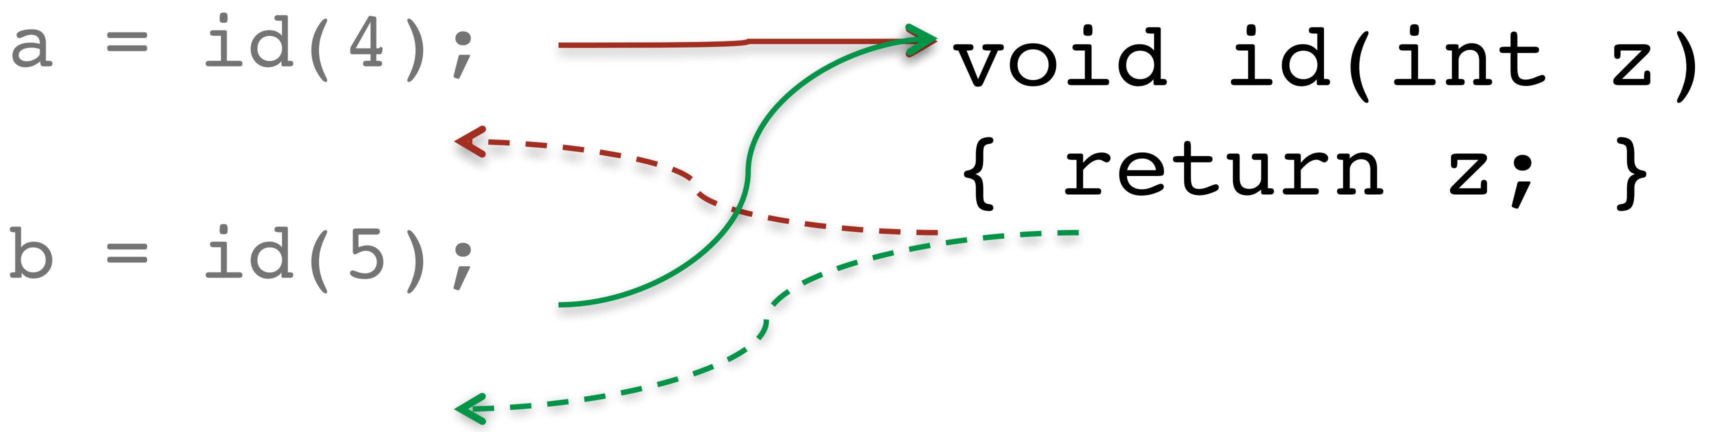
```
void red(int x)
{
..
}
```

```
void green()
{
  green();
  yellow();
}
```

Context sensitive distinguishes 2 different calls to red(-)

[Brumley'15]

Context Sensitive Example



```
a = id(4);

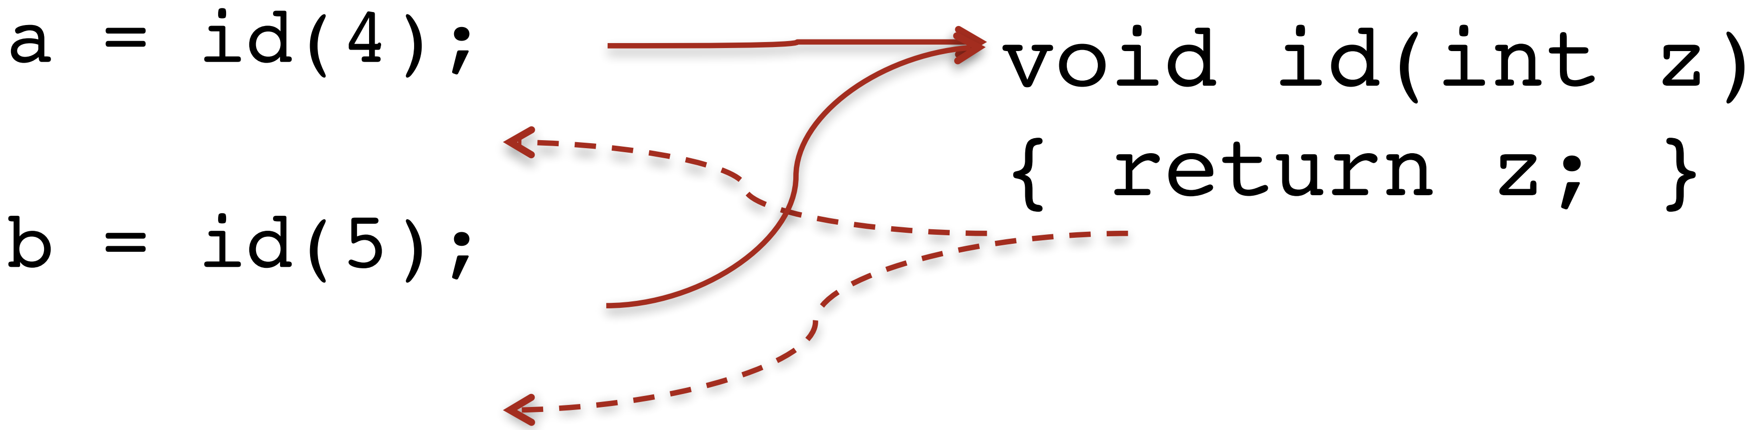
b = id(5);
```

```
void id(int z)
{ return z; }
```

Context-Sensitive

(color denotes matching call/ret)

Context sensitive can tell one call returns 4, the other 5



```
a = id(4);

b = id(5);
```

```
void id(int z)
{ return z; }
```

Context-Insensitive

(note merging)

Context insensitive will say both calls return {4,5}

[Brumley'15]

Flow Sensitive

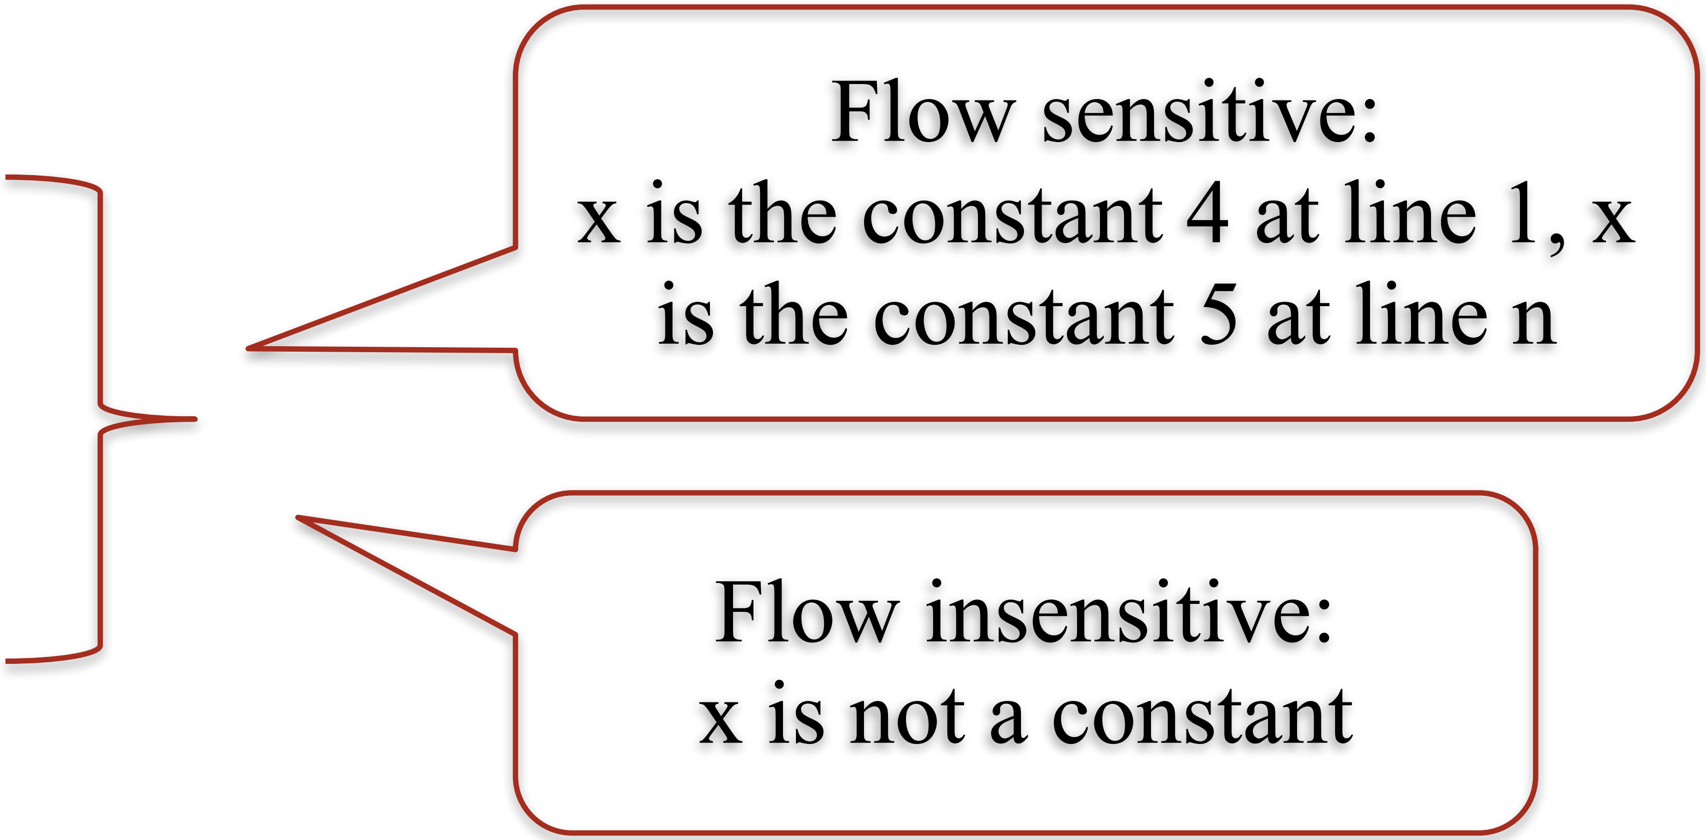
- A flow sensitive analysis considers the order (flow) of statements
- Examples:
  - Type checking is flow insensitive since a variable has a single type regardless of the order of statements
  - Detecting uninitialized variables requires flow sensitivity

```
x = 4;
....
x = 5;
```

Flow sensitive can distinguish values of x, flow insensitive cannot

Flow Sensitive Example

```
1. x = 4;
....
n. x = 5;
```



Flow sensitive:
x is the constant 4 at line 1, x is the constant 5 at line n

Flow insensitive:
x is not a constant

[Brumley'15]

Path Sensitive

- A path sensitive analysis maintains branch conditions along each execution path
  - Requires extreme care to make scalable
  - Subsumes flow sensitivity

[Brumley'15]

Path Sensitive Example

```
1. if(x >= 0)
2.    y = x;
3. else
4.    y = -x;
```

path sensitive:
y >= 0 at line 2,
y > 0 at line 4

path insensitive:
y is not a constant

[Brumley’15]

Precision

Even path sensitive analysis approximates behavior due to:

- loops/recursion
- unrealizable paths

```
if(a^n + b^n = c^n && n>2 && a>0 && b>0 && c>0)
    x = 7;
else
    x = 8;
```

Unrealizable path.
x will always be 8

[Brumley’15]

Control Flow Integrity (Analysis)

CFI Overview

- Invariant: Execution must follow a path in a control flow graph (CFG) created ahead of run time.

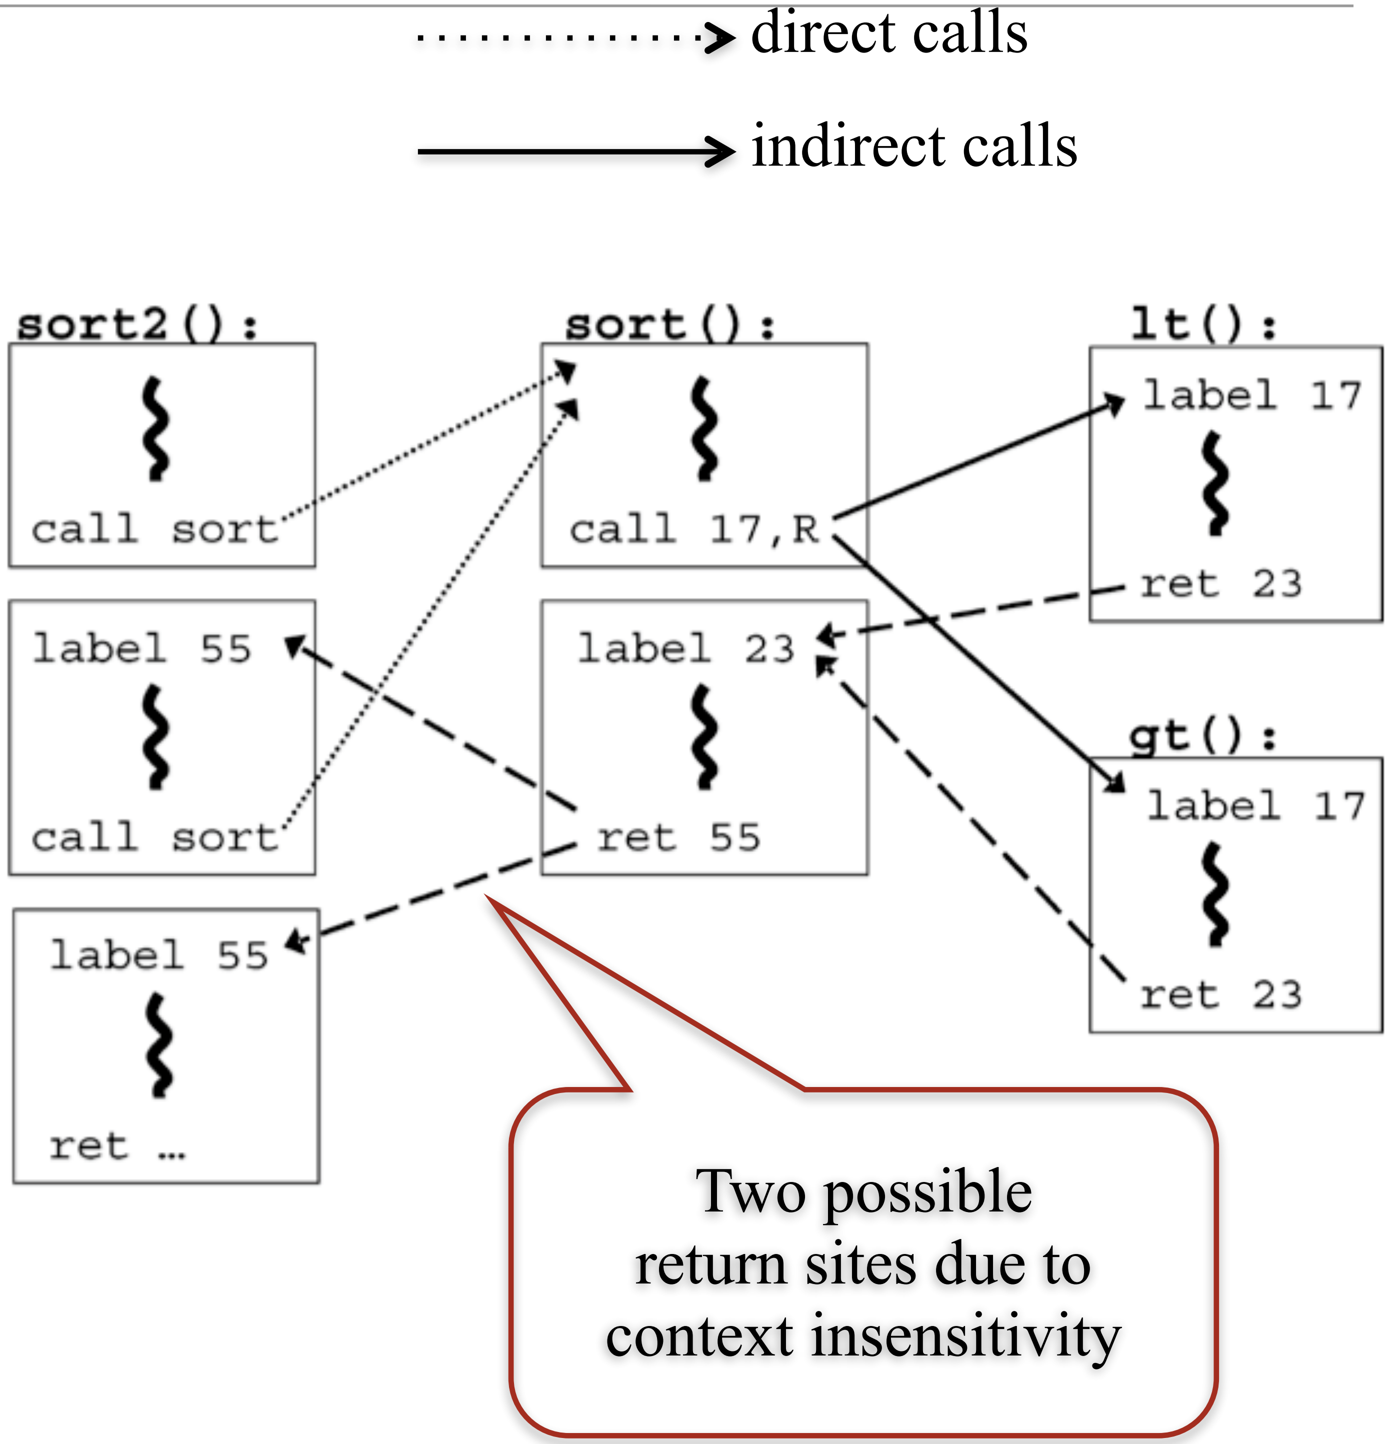
- Method:
  - build CFG statically, e.g., at compile time
  - instrument (rewrite) binary, e.g., at install time
    - add IDs and ID checks; maintain ID uniqueness
  - verify CFI instrumentation at load time
    - direct jump targets, presence of IDs and ID checks, ID uniqueness
  - perform ID checks at run time
    - indirect jumps have matching IDs

[Brumley’15]

Build CFG

```
bool lt(int x, int y) {
    return x < y;
}
bool gt(int x, int y) {
    return x > y;
}

sort2(int a[], int b[], int len)
{
    sort( a, len, lt );
    sort( b, len, gt );
}
```

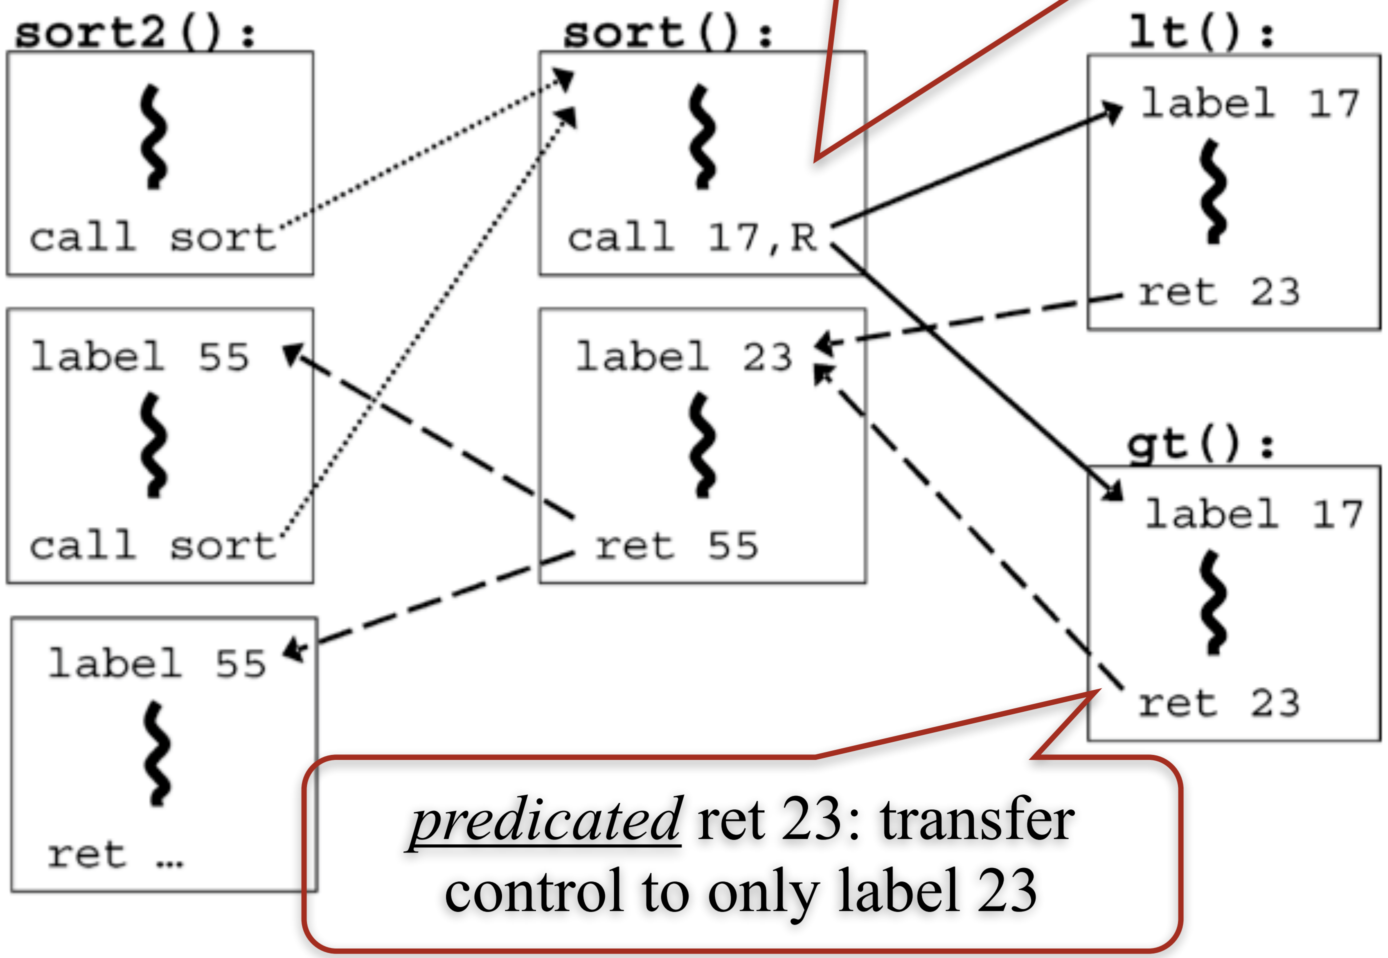


Two possible return sites due to context insensitivity

Instrument Binary

```
bool lt(int x, int y) {
    return x < y;
}
bool gt(int x, int y) {
    return x > y;
}

sort2(int a[], int b[], int len)
{
    sort( a, len, lt );
    sort( b, len, gt );
}
```



predicated call 17, R: transfer control to R only when R has label 17

predicated ret 23: transfer control to only label 23

- Insert a unique number at each destination
- Two destinations are equivalent if CFG contains edges to each from the same source

[Brumley'15]

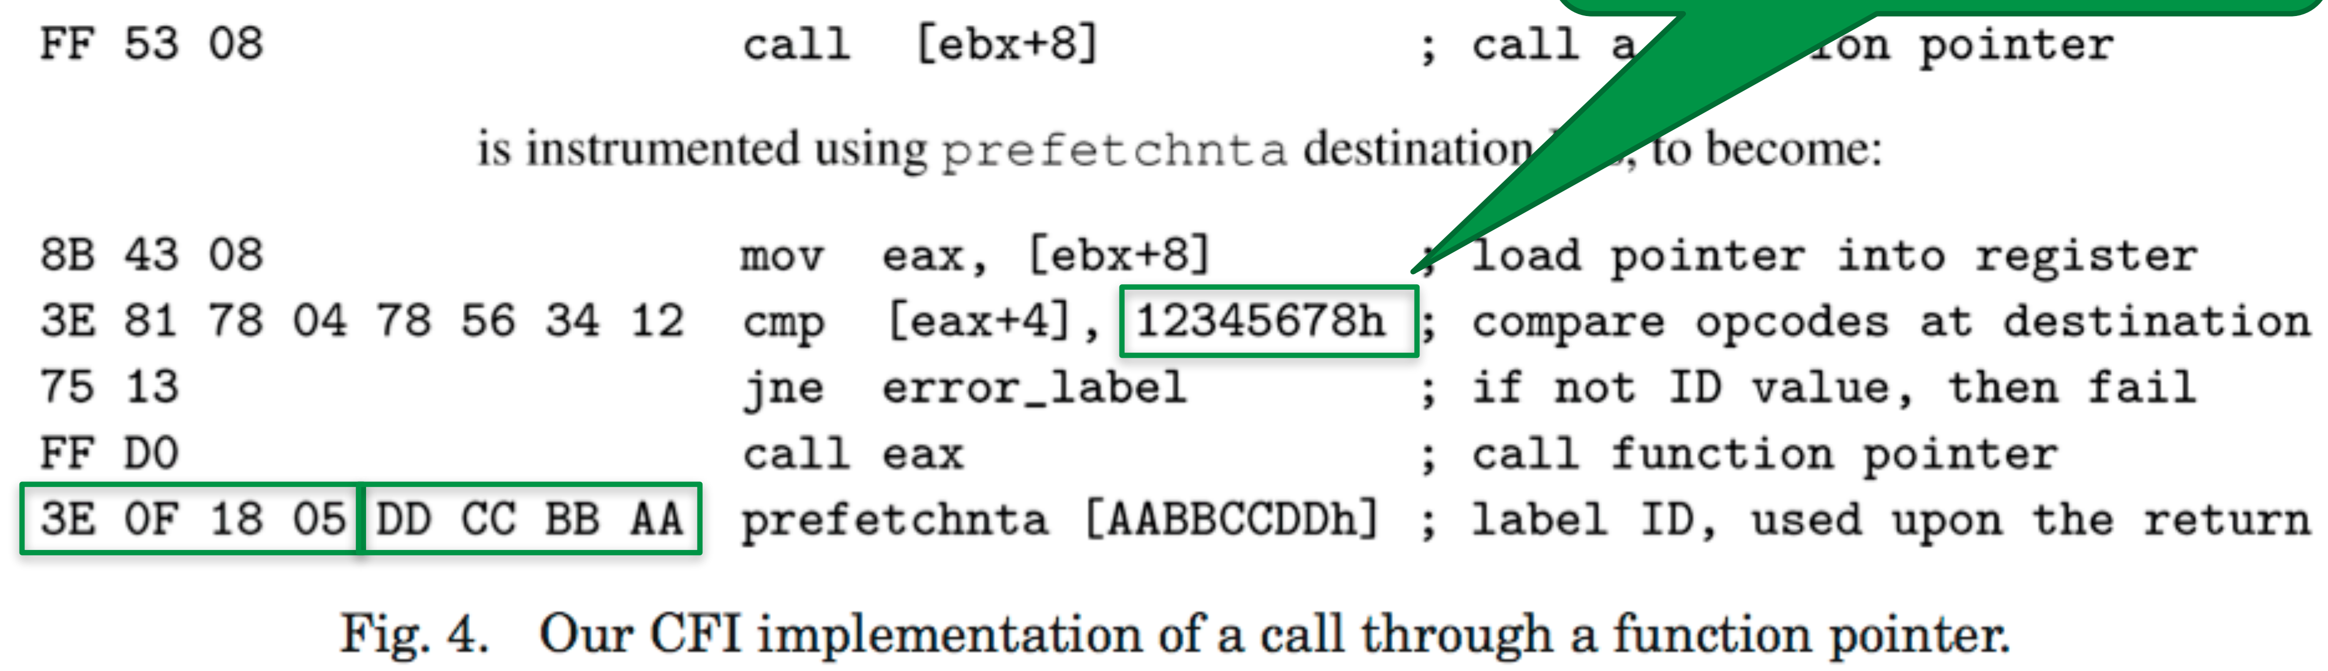
Verify CFI Instrumentation

- Direct jump targets (e.g. call 0x12345678)
  - are all targets valid according to CFG?
- IDs
  - is there an ID right after every entry point?
  - does any ID appear in the binary by accident?
- ID Checks
  - is there a check before every control transfer?
  - does each check respect the CFG?

easy to implement correctly => trustworthy

[Brumley'15]

ID Checks



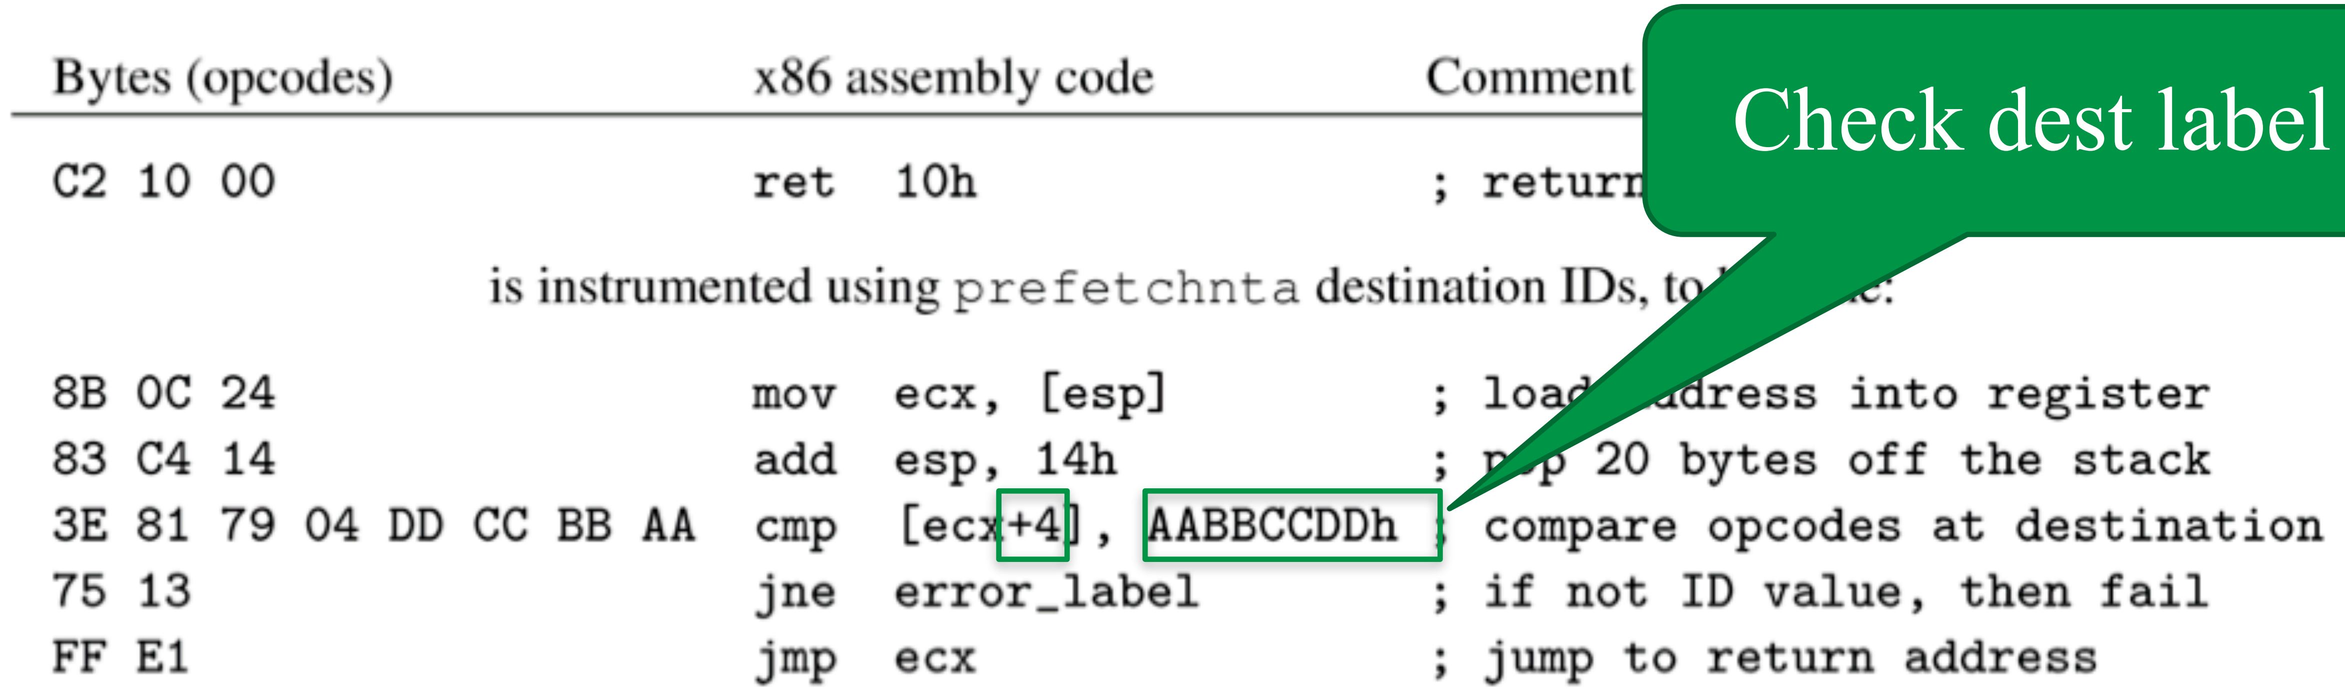
```
FF 53 08                call   [ebx+8]          ; call a          ion pointer
```

is instrumented using prefetchnta destination   , to become:

```
8B 43 08                mov   eax, [ebx+8]      ; load pointer into register
3E 81 78 04 78 56 34 12 cmp   [eax+4], 12345678h ; compare opcodes at destination
75 13                   jne   error_label       ; if not ID value, then fail
FF D0                   call eax                ; call function pointer
3E 0F 18 05 DD CC BB AA prefetchnta [AABBCCDDh] ; label ID, used upon the return
```

Fig. 4. Our CFI implementation of a call through a function pointer.

Check dest label



```
Bytes (opcodes)         x86 assembly code       Comment
C2 10 00                ret   10h               ; return
```

is instrumented using prefetchnta destination IDs, to   e:

```
8B 0C 24                mov   ecx, [esp]        ; load   ddress into register
83 C4 14                add   esp, 14h          ;   p 20 bytes off the stack
3E 81 79 04 DD CC BB AA cmp   [ecx+4], AABBCCDDh ; compare opcodes at destination
75 13                   jne   error_label       ; if not ID value, then fail
FF E1                   jmp   ecx               ; jump to return address
```

Check dest label

Performance

- Size: increase 8% avg
- Time: increase 0-45%; 16% avg

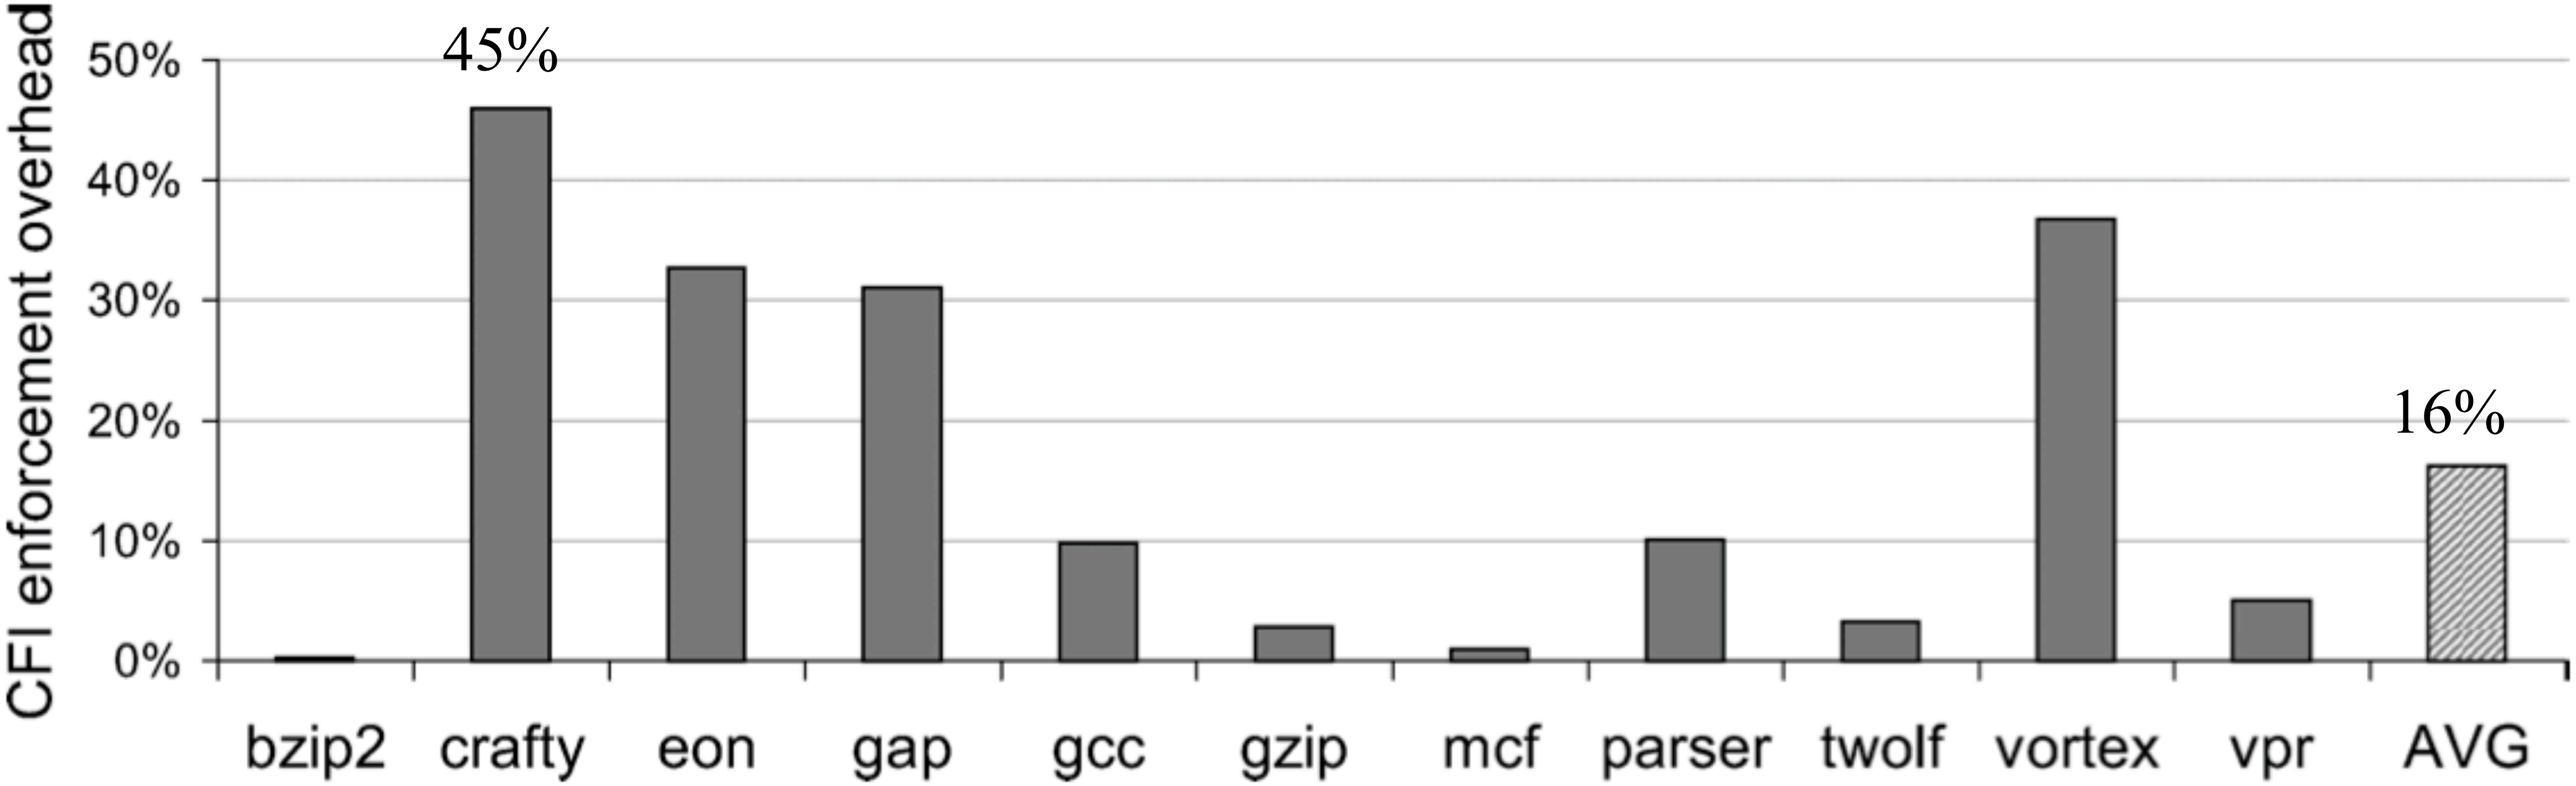


Fig. 6. Execution overhead of inlined CFI enforcement on SPEC2000 benchmarks.

Security Guarantees

- Effective against attacks based on illegitimate control-flow transfer
  - buffer overflow, ret2libc, pointer subterfuge, etc.

Any check becomes non-circumventable.

- Allow data-only attacks since they respect CFG!
  - incorrect usage (e.g. printf can still dump mem)
  - substitution of data (e.g. replace file names)

[Brumley'15]

Software Fault Isolation

- SFI ensures that a module only accesses memory within its region by adding checks
  - e.g., a plugin can accesses only its own memory

```
if(module_lower < x < module_upper)
    z = load[x];
```

SFI Check

- CFI ensures inserted memory checks are executed

[Brumley’15]

Inline Reference Monitors

- IRMs inline a security policy into binary to ensure security enforcement

- Any IRM can be supported by CFI + Software Memory Access Control
  - CFI: IRM code cannot be circumvented

    +

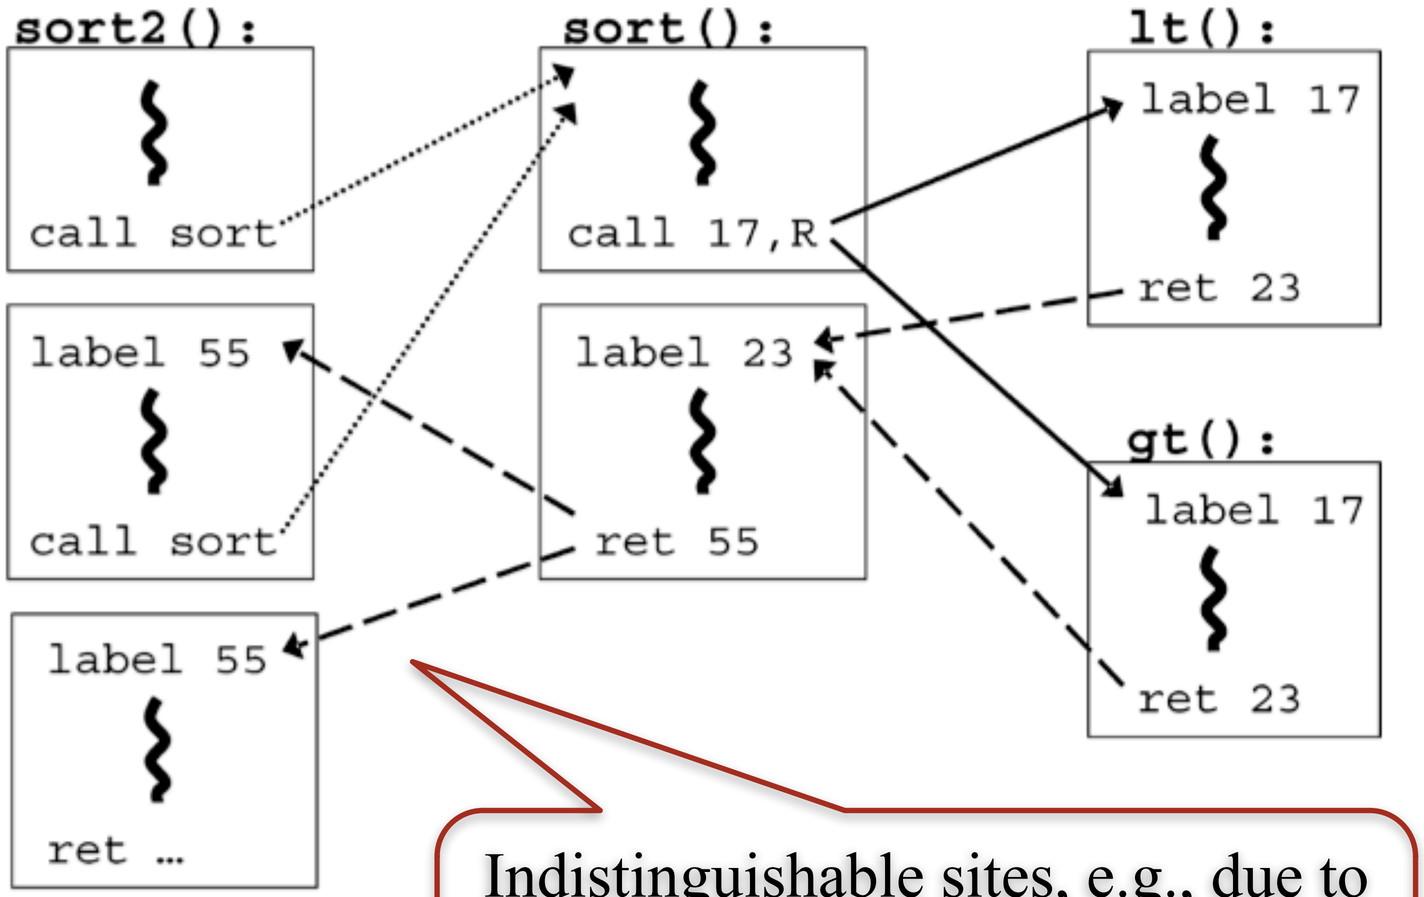
  - SMAC: IRM state cannot be tampered

Accuracy vs. Security

- The accuracy of the CFG will reflect the level of enforcement of the security mechanism.

```
bool lt(int x, int y) {
    return x < y;
}
bool gt(int x, int y) {
    return x > y;
}

sort2(int a[], int b[], int len)
{
    sort( a, len, lt );
    sort( b, len, gt );
}
```



Indistinguishable sites, e.g., due to lack of context sensitivity will be merged

Context Sensitivity Problems

- Suppose A and B both call C.
- CFI uses same return label in A and B.

- How to prevent C from returning to B when it was called from A?
- Shadow Call Stack
  - a protected memory region for call stack
  - each call/ret instrumented to update shadow
  - CFI ensures instrumented checks will be run

[Brumley'15]

CFI Summary

- Control Flow Integrity ensures that control flow follows a path in CFG
  - Accuracy of CFG determines level of enforcement
  - Can build other security policies on top of CFI
